THE LANCET.

Journal of British and Foreign Medicine, Surgery, Obstetrics, Physiology, Chemistry, Pharmacology, Public Health, and News.

IN TWO VOLUMES ANNUALLY.

VOL. I. FOR 1914.

NINETY-SECOND YEAR.

SAMUEL SQUIRE SPRIGGE, M.A., M.D. CANTAB.,
EDITOR.

LONDON:
TED AND PUBLISHED BY THE PROPRIETORS, AT THE OFFICES OF "THE LANCET," No 423, STRAND, AND
Nos. 1 & 2, BEDFORD STREET, STRAND.

INDEX TO VOLUME I., 1914.

Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Bicycle and Cycle, Child and Infant, Bronchocele, Goitre, and Thyroid, Diabetes, Glycosuria, and Sugar, Eye, Ophthalmic, and Vision, &c., &c.

ON

PROPHYLACTIC INOCULATION AGAINST PNEUMOCOCCUS INFECTIONS,

AND ON THE RESULTS WHICH HAVE BEEN ACHIEVED BY IT.[1]

BY SIR ALMROTH E. WRIGHT, M.D., F.R.S.,

IN CONJUNCTION WITH

W. PARRY MORGAN, M.B. CANTAB., L. COLEBROOK, M.B. LOND., AND R. W. DODGSON, M.D. LOND.

GENTLEMEN,—I have the honour herewith to lay before you the second, and concluding, part of my Report on the Causation, Prophylaxis, and Treatment of the Pneumonia which affects the Native Labourers, and in particular the Tropical Native Labourers, in the Rand Mines.

In the introduction to Part I. the broad principles which must guide us when confronting bacterial disease were elucidated. It was explained that whether the object we have in view is prophylaxis or cure—that is, whether, as in prophylactic inoculation, we endeavour to kill off microbes immediately upon their entrance into the body before they have produced disease; or whether, as in *medicine practised as a science, we try to* kill off bacteria when, by invading the body in large numbers, they have already produced disease—our task is to supply to the organism substances which are specifically *bacteriotropic*—that is, substances which make a chemical attack specifically upon the microbes of disease.

We saw that in connexion with each several disease two paths of research open out before us. On the one hand, there is the path of *pharmacotherapy.* Following this, we may come to an effective and non-poisonous specifically bacteriotropic drug. There is, on the other hand, the path of *immuno-therapy.* Following this, we may come to an effective vaccine—i.e., to a vaccine which will, when administered in a proper dose, stimulate the chemical machinery of the patient to elaborate the required *specifically bacteriotropic substances.*

We have here to deal with the *immuno-therapy* of pneumococcus infections, and in particular with the employment of vaccines in the prophylaxis and treatment of pneumonia. It will not be amiss to begin by setting out the evidence which establishes that the pneumococcus is the microbe which is the causal agent of the pneumonia on the Rand. (Table I.)

TABLE I.—*Data of Blood Cultures and Lung Puncture Cultures undertaken upon Cases of Pneumonia in Tropical Natives treated in the Hospital of the Witwatersrand Native Labour Association.*[2]

Nature of the bacteriological observation.	Number of cases examined.	Number of cases in which the pneumococcus was found.	Number of cases in which the cultures remained sterile.	Number of cases in which a microbe other than the pneumococcus was found.
Blood cultures (1 to 20 c.c. of *blood*).	380	99 *	277 †	4 ‡
Lung puncture cultures.	53	31 §	18 ‖	1 ‡

* Of these, 56 (i.e., 56 per cent.) succumbed. † Of these, 76 (i.e., 27·5 per cent.) succumbed. ‡ The micro-organism which grew was in each case one of the coli group. § Of these, 10 succumbed. ‖ Of these, 6 succumbed.

The nature of the bacterial infection which was to be combated having been set at rest, our principal task stood out clearly before us. It was to prepare vaccines of the pneumococcus; to ascertain, if possible, what was the best form of vaccine; and above all to determine the effective and, so far as might be possible, the *optimum* dose of the vaccine, and the best method of application.

We may with advantage begin with a brief description of the methods we adopted in preparing the vaccine; and we may then, before dealing specifically with immunisation against the pneumococcus, call attention to those broad general principles with regard to dosage and the *modus operandi* of vaccines which would appear to be deducible from the experience won in connexion with immunisation against other bacterial infections.

SECTION I.—*Preparation of Pneumococcus Vaccines.*

We experimented somewhat extensively with a view to selecting for use a medium which should give a very copious culture of pneumococcus. Varying in a methodical manner the peptone, extractives, and alkali of ordinary peptone broth, and then making to such media graduated additions of human serum, we found that very copious cultures of pneumococcus were regularly obtained with a medium which contained (*a*) 1 per cent. of *peptone and 1 per cent. of lemco*; (*b*) 2½ *to* 5 *per* cent. of human serum; and (*c*) an amount of alkali fixed by neutralising to phenolphthalein, and then adding 6 c.c. of normal acid solution to each litre of medium.

During the first couple of months of our work in Johannesburg we worked with a medium composed as above; but finding that we obtained much more copious cultures by adding up to 1 per cent. of glucose to the above mentioned medium, we employed such serum glucose broth in most of our subsequent work. We would, however, point out in this connexion that where such a serum glucose broth is employed it is necessary to be constantly *on the watch against the occurrence of autolytic* processes which go, it would seem, hand in hand with the development of acid in the culture medium. For these autolytic processes[3] may, even they stop short of an actual disintegration of the microbes, deprive the bacteria of their power of staining with aniline dyes, and so give rise to formidable fallacies in standardising the vaccines.

Our vaccines were in all cases made from cultures which had grown for 24 to 30 hours. They were standardised by enumeration by the now familiar method devised by one of us. The cultures were killed by exposure to a temperature of 55° to 56° C. for half an hour. An addition of ½ per cent. of carbolic acid was then made to the vaccines.

SECTION II.—*Generalisations with Reference to the Modus Operandi and Dosage of Vaccines, and Considerations suggested by Experience won in connexion with Prophylactic and Therapeutic Inoculation generally.*

Whenever an *antigen*—and we mean by an "antigen" an alien molecule whose incorporation incites the chemical machinery of the body to immunising response—comes into operation upon the tissues, these react to that attack by producing *antigeni-tropic* and *antigeni-clastic substances*—i.e., substances which combine with, render inert, and break down the antigen. It is a characteristic feature of such reactions of immunisation that the output of antigeni-tropic and antigeni-clastic substances is in the ordinary case much in excess of what would suffice for the neutralisation and disintegration of the quantum of antigen which call forth their production.

---

[1] Being Part I[illegible] Asso[illegible] laxi[illegible] Labo[illegible] Min[illegible] and 21st (p. 1701), 1912.

[3] [illegible] in which autolysis has occurred did not exert any bactericidal power upon the pneumococcus.

The reaction which is evoked by the inoculation of a bacterial vaccine is merely a special case of immunising response. By it bacteriotropic substances, and among these substances which break down the bacterial protoplasm—bacterioclastic substances—are produced. And in the ordinary case the inoculated organism is, at the end, left in possession of an increased store of these protective substances. We take advantage of this in prophylactic and therapeutic inoculation.

Passing from the consideration of the *modus operandi* of bacterial vaccines to their dosage it is essential to realise *in limine* that we must be on our guard against importing into the study of this question preconceptions derived from experience with drugs. When, for instance, we come upon the fact that there are reported, in connexion with therapeutic inoculation, good results from the administration of minimal doses of vaccines, and also equally good results from the administration of doses 1000 to 100,000 times larger, it would be quite wrong to assert upon the basis of an experience with drugs that these divergent reports are contradictory and irreconcilable. To rush to such a conclusion would be to close one's eyes to the fact that provision is made in the organism for combating, on the one hand, trivial localised infections, [illegible]nd, on the other hand, severe septicæmic infec[illegible]—in other words, for making immunising [illegible]nse both to small and to relatively large [illegible] of bacterial antigens.

[illegible]gain, it would be fatal to conclude from an experience of drugs that, if a particular dose of vaccine produced serious symptoms, a tenfold larger dose would of necessity produce graver symptoms, and still larger doses a rapidly fatal result. That would be to leave out of reckoning the fact that there are in the organism compensating arrangements; and that there is provision for ignoring, or at least for provisionally ignoring and postponing the attack upon, massive bacterial infections which are upon too large a scale to be disposed of immediately.

In connexion with the dosage of bacterial vaccines we have to guide ourselves by a series of general principles, which have either emerged in the course of the general study of immunisation or have been derived from the direct measurements of the bacteriotropic power of the blood made in connexion with the inoculation of bacterial vaccines. Of these general inferences, the following are perhaps for us the most important.

In the case where a bacterial vaccine is incorporated in minute quantity directly into the subcutaneous tissue one would on *a priori grounds* anticipate that the whole of it would be "*anchored*" at the seat of inoculation, with the result that the immunising response would be confined to this region and its lymph channels; and with the further fundamentally important practical result that the effect produced upon the general system by the inoculation would not differ from that which would be produced by a conveyance of a small quantum of protective substances into the blood.

The inference that the *minimal effective dose* of vaccine calls forth only a *local immunising response* is confirmed by the fact that, so far as we know, the only change in the blood after the injection of such a dose is a rise in its bacteriotropic power. When a larger dose of bacterial vaccine is inoculated into the subcutaneous tissue—i.e., when the dose of bacterial antigen exceeds that quantum which can be anchored at the seat of inoculation—one would expect, first, an influx of vaccine or of its derivative antigen into the blood-stream; and after this, in the ordinary case, as soon as the antigen has come into operation upon the general tissues, a *systemic immunising response*, with an inflow of protective substances into the blood. We have confirmation of this anticipation in the fact that we obtain after the inoculation of a moderate dose of vaccine, first, a *negative* and afterwards a *positive phase* of bacteriotropic power—in other words, *first*, a phenomenon of de-immunisation and then a phenomenon of immunisation. But clearly the achievement of a systemic immunising response would be conditional upon the antigen remaining free in the blood; and upon the concentration of the antigen being, after dilution with the whole volume of blood, such as to permit of its coming into effective operation upon the tissues.

There are here two possibilities. There is, on the one hand, the possibility that the antigen might be too concentrated at the seat of inoculation to produce a local immunising response; and that it might, after dilution with the whole volume of the blood, and eventual neutralisation there, be reduced to the point of ineffectiveness. We should in such a case have neither a negative nor a positive phase. There is, on the other hand, the possibility that the antigen might, even after it had been diluted with the whole volume of the blood, still be too concentrated to be effective. We should in this case expect a negative phase which would not be followed up by a positive phase. Only methodical experimentation could show exactly up to what point these theoretical possibilities are realised. It is, however, practically certain that an overpowering dose of vaccine—typhoid vaccine is the vaccine we have here in view—produces a well-marked and enduring negative phase.

We have not yet come to the end of the complications which have to be unravelled. We have to account also for the facts—(*a*) that a dose which in one man produces no constitutional commotion will in another produce severe disturbance; (*b*) that after a certain dose of vaccine has been arrived at, further increments produce no further increase in the constitutional disturbance, and no further reduction in the bacteriotropic power of the blood; (*c*) that the infected organism is generally much more sensitive than the uninfected organism, both to toxic effect of the homologous vaccine, and also to its de-immunising and immunising effect; (*d*) that the organism when wasted by severe and long-lasting infection becomes again more tolerant of the vaccine; and (*e*) that a similar tolerance is established in a patient whose blood has been tampered with by the incorporation of large doses of vaccine.

In connexion with this series of facts we shall do well to reflect that before a vaccine can take effect upon the tissues, and before an immunising response can be evoked from these, the bacterial protoplasm would have to be brought into solution by the blood-fluids. Further, the bacterial extract which bacteriolysis would then have furnished might, perhaps, have to be decomposed in such a way as to set free the antigen.

Three different operative factors might here influence the result: (*a*) Each different species of microbe might offer a different resistance to bacteriolysis, and each resulting bacterial extract a different resistance to bacterioclasis. (*b*) The mode in which the vaccine is incorporated might tell upon the result. In the case where it is incorporated into, and remains lodged in, the subcutaneous tissue one might, inasmuch as here only a small quantum of lymph comes into operation upon the vaccine, *expect to obtain, at best, tardy and incomplete* bacteriolysis and bacterioclasis. Where the vaccine is carried on into the circulation, or is incorporated directly into the blood stream, one might expect a more rapid and complete setting free of the antigen. (*c*) Natural differences in the bacteriolytic and bacterioclastic powers of the blood of different individuals, and also differences referable to foregoing immunisations or de-immunisations, might come into play.

All these different considerations suggest to the mind that we have to consider in inoculating not the actual quantum of vaccine we incorporate, but the quantum of antigen which will be set free from it in the organism of the patient. This hypothesis would fit the fact that there always comes, in the case where progressively larger doses of vaccines are administered, a point where an increase in the dose ceases to call forth a greater response. Our hypothesis would explain also the difference in the behaviour of different vaccines. We have in view here the fact that we obtain with a vaccine like typhoid vaccine, which is readily dissolved and presumably broken up by the blood fluids, a local inflammation at the seat of inoculation, and when a sufficiently large dose is inoculated, also constitutional disturbance with a negative phase; while we obtain neither local inflammatory reaction nor negative phase disturbance when we are dealing with a vaccine which the patient's blood is incompetent to dissolve and decompose. Our hypothesis would explain also the fact that a patient who has, as a result of immunisation or auto-immunisation, acquired a greater bacteriolytic and bacterioclastic power, evinces an increased sensibility to the vaccine. For this is what might reasonably be expected to occur if antigen was set free and a corresponding quantum of antidotal substances was not available to neutralise it. And, in point of fact, this would appear to be the condition encountered in the ordinary tuberculous patient. We have here in the blood an increased bacterioclastic power,[4] and in association with this a great sensitiveness to the epidermal application of tuberculin (Pirquet's phenomena); a greater constitutional sensibility to an incorporation of tuberculin; and a greater susceptibility to its immunising and de-immunising action.

Having once recognised that increased sensitiveness to a bacterial vaccine may be an expression of progress—of course, only very lop-sided progress—in immunisation, the way is open to the recognition of the possibility that the condition of tolerance which characterises the patient who is wasted with a long infection, or has been treated with large doses of vaccine, may mean a reduction in the bacterioclastic power of the blood, and so a retrogression in immunity. The failure to react to tuberculin, and the absence of the Pirquet reaction in old-standing and desperate cases of tuberculosis, would perhaps be explicable in this manner.

In conclusion, it may be pointed out that while some of the increased sensibility of the infected to their homologous vaccine may be put down to the account of increased bacterioclastic power, we must recognise that the constitutional disturbance which supervenes in the infected is due primarily to the *fact that inoculation produces in them always a* secondary auto-inoculation. We can account for the occurrence of such a secondary auto-inoculation when we consider that there must inevitably follow upon any rise in the bacterioclastic power of the blood a breaking down of microbes and a setting free of antigen in the focus of infection which would correspond to a supplementary inoculation. It will accordingly be necessary when reckoning the dose for an infected patient to calculate for the dose which we administer being reinforced by the quantum of antigen which will be liberated in the focus of infection.

In bringing this section to a close it may be pointed out that the general principles we have here been considering must be kept in view not only by the practical worker, but also by the statistician who analyses the results of inoculation. Certain other general considerations in connexion with the dosage and *modus operandi* of vaccines will suggest themselves as we develop our theme.

SECTION III.—*Account of the Laboratory Work undertaken with a View to Finding the Optimum Dose of Pneumococcic Vaccine and the Best Scheme of Administration.*

When we set ourselves the task of finding out what is the optimum dose of a vaccine and the best scheme of administration we can employ one or other of two different methods. We can either—selecting as best we can (which means by a more or less haphazard procedure) a "reasonable" dose and scheme of administration—directly undertake a mass experiment, with the idea of afterwards modifying our dose and programme of inoculation in the light of the statistical results which will come in. Or we can in connexion with each small group of inoculations test the effects we are producing upon the blood with a view to finding out in this way what dose of vaccine and what scheme of inoculation furnish the best curve of immunisation. It will be obvious that if we can adopt this latter procedure, and are not quite unsuccessful in our investigations, the possibilities of failure will be reduced and the prospect of achieving the optimum results will be more favourable. Influenced by this consideration our plan of action was made up, and we addressed ourselves immediately to a preliminary study of the blood in its relation to the pneumococcus in order to prepare ourselves to measure the rise and fall in protective substances elaborated in response to each different dose of pneumococcus vaccine and each different method of administration.

With these thoughts and designs we investigated in succession: (*a*) *the agglutinating power of the serum;* (*b*) the *bactericidal power of the serum;* and (*c*) the *opsonic power of the serum.* Further—

---

[4] We have found—and this is in consonance with the results of experiments carried out by F. Meyer and Schmitz (Deutsche Medicinische Wochenschrift, 1912, No. 42, p. 1963) on rabbits—that tuberculin, which has been digested *in vitro* at 37° C. with the serum of a patient, gives a marked Pirquet reaction on the skin of a healthy individual who is insensitive to a control insertion carried out simultaneous on another portion of his skin with the same concentration of untreated tuberculin.

breaking here new ground—we investigated the *phagocyto-bactericidal power* of the unaltered, artificially altered, and reconstituted blood.

Agglutinating Power of the Serum.

We may summarise the result of a number of examinations made directly *ad hoc*, and of a much larger number made incidentally in connexion with measurements of the opsonic power of the blood, by saying that the agglutination reaction is with the pneumococcus only very irregularly obtained. Working with subcultures from the blood- and lung-puncture cultures which were in question above, we found that the vast majority of these gave no agglutination reaction with the blood of any patient. Moreover, in the case of those exceptional cultures which gave agglutination, we obtained the reaction not only with a large number of sera from pneumonic patients, but also with a number of normal sera. By consequence we put aside the agglutination test as one that could not be utilised for the purpose of estimating the effect produced by pneumococcus vaccines.

Bactericidal Power of the Serum.

Previous experiments having taught us that the normal human serum when mixed volume for volume with progressive dilutions of the bacterial suspension exerts no bactericidal effect upon the pneumococcus, we elaborated, for the purposes of the present research, a technique which allows of the serum being brought into application upon the pneumococci in a practically undiluted condition. The technique which realises this requirement may here be briefly described.

The apparatus consisted of looped pipettes, such as are described and figured by one of us in his text-book of technique.[5] A 5 c.mm. volume was marked off upon the stem of each pipette by introducing, by the aid of an automatic pipette, 5 c.mm. f mercury into its distal end, and then inscribing pencil mark opposite the upper level of the mercury.

The procedure is then as follows. After resterilising the stem and fitting a teat to the pipette, there is aspirated into the barrel a sufficient quantity of 1 per cent. serum broth to half fill it. There is then aspirated into the capillary stem—which is, when the broth has passed up into the barrel, left empty—5 c.mm. of the serum to be ested. This done, a bubble of air is drawn into the mouth of the pipette; this is then dipped into a suspension of the pneumococcus placed ready to hand in a tubule, and 5 c.mm. of this suspension is taken into the capillary stem. This done, the distal end of the pipette is brought up against the inner wall of an empty sterile tubule placed upright in plasticine, and now the 5 c.mm. of the pneumococcus suspension is, by carefully regulated pressure upon the teat, expelled, while the serum, which follows after, is carried forward to the very orifice so that it may incorporate into itself all the microbes which the suspension leaves behind on the wall of the tube. This accomplished, the serum is, by relaxing the pressure on the teat, carried back into the middle third of the stem of the pipette so as to allow of our sterilising the distal end and sealing it up in the flame.

By this technique we can, if we are employing a series of graduated dilutions of a bacterial suspension. incorporate into our 5 c.mm. volumes of serum graduated numbers of microbes.

Two further points in connexion with the technique remain to be explained:—

(1) After the serum has operated upon the microbes which have been incorporated into it for such period as we may have decided upon (in our experiments the serum was generally allowed to operate upon the microbes for four to five hours) we fit a teat to the tube; break off the tip of the capillary stem; draw up the serum into the nutrient fluid in the barrel of the pipette; and then incubate for 24 hours to ascertain whether the microbes have, or have not, been killed by contact with the serum.

In order to make all go off smoothly in opening up the pipette, we employ one or other of the following devices: (*a*) we draw out the end of the capillary stem into a hair-fine tube before imposing the collapsed teat; or (*b*) we employ a perforated teat; or (*c*) we mark the position of our column of serum by inscribing a pencil mark on the stem of the pipette; then impose a partially collapsed teat; and then, before breaking off the tip of the capillary stem, regulate by pressure on the teat the air-pressure in the pipette in such a manner as to bring our column of fluid back accurately to the level of the pencil mark.

(2) To find out the number of microbes which we are dealing with in our bactericidal estimation we take another series of similarly graduated pipettes, using enough of these to have two or more for each of the more diluted bacterial suspensions. We fill in these pipettes with the same nutrient fluids, and then—varying the technique from that described above only in the respect that we omit the volume of serum—we draw into separate tubes 5 c.mm. of each successive bacterial suspension; expel this, driving forward the nutrient fluid to the mouth of the tube, so as to incorporate into it all the microbes which remain behind on the walls; and then place the series of pipettes in the incubator.

With this method we tested in all 264 samples of serum; 41 of these were derived from ourselves, 20 were derived from natives in different stages of pneumonia, 27 were derived from uninoculated tropical natives, and 176 were derived from tropical natives who had been inoculated once or oftener with different doses of pneumococcus vaccine. In the case of the sera derived from the last two classes of persons, we employed in each experiment the pooled serum of a group of two to five patients, counting this, of course, only as one serum. In the case of the sera derived from pneumonic native patients or from ourselves (who served in each case as controls) each serum was taken in hand separately. The results of the bactericidal estimations thus undertaken may be tabulated as follows:—

TABLE II.

Variety of serum.	Total number of observations.	Number of observations in which no microbes were killed by 5 c.mm. of serum.	Number of observations in which 1 to 3 microbes were killed by 5 c.mm. of serum.	Number of observations in which 3 to 9 microbes were killed by 5 c.mm. of serum.	Number of observations in which over 9 microbes were killed by 5 c.mm. of serum.
Normal European.	41	36	4	1	0
Native pneumonic patients.	20	11	9	0	0
Normal tropical natives.	27	19	8	0	0
Inoculated tropical natives.	176	161	15	0	0

We may obviously conclude from these observations: (*a*) that the normal serum of whites and tropical natives does not exert any appreciable bactericidal effect upon the pneumococcus; and (*b*) that the serum of the natives does not acquire any appreciable *bactericidal* power under the influence of either natural infection or inoculation. At the same time we would point out that, while there is no bactericidal power in the serum which is worth while taking into account in connexion with the study of the effects of inoculation and auto-inoculation, closer study reveals that the sera which have a high opsonic power, and which manifest from time to time such slight bactericidal effects as are shown in the table above, may perhaps possess an appreciable power of inhibiting the growth of the pneumococcus. It may, for instance, be noted that the serum of A. E. W., which in 17 bactericidal experiments gave on three occasions evidence of a slight bactericidal power (5 c.mm. of the serum once killing up to 9 pneumococci), was found when admixed with broth (in proportions of 40 and higher percentages of serum to 60 and lower percentages of broth) to inhibit or retard the growth of the pneumococcus, while the blood of L. C., which gave in 10 bactericidal experiments completely negative results, failed to exhibit any growth-inhibiting power. Similar indications were obtained also with the blood of another laboratory worker (A. R. F.).

---

[5] Wright's Technique of the Teat and the Capillary Glass Tube. London: Constable. 1912.

Opsonic Power of the Serum.

We had anticipated that the measurement of the opsonic power of the serum would have furnished us with a valuable method for making an evaluation—*of course, only a partial evaluation*—of the protective substances produced in response to the inoculation of vaccines or auto-inoculation. We obtained, however, from much assiduous work devoted to the measurement of the pneumo-opsonic power of the blood of the inoculated and uninoculated natives, and native pneumonic patients, a quite lamentably small harvest of suggestive and interesting facts. It will be worth while, even if only for the sake of the facts discovered by the way, to set out the difficulties which we encountered and the procedures which we resorted to to circumvent those difficulties.

Difficulties which present themselves in connexion with the measurement of the pneumo-opsonic power of the serum.—(*a*) The *first* difficulty which presents itself is one to which Rosenow has called attention in the first of the very valuable series of memoirs which he has published on the pneumococcus. The difficulty in question lies in the fact that cultures of pneumococcus freshly isolated from pneumonic cases often fail to give any phagocytosis. After having been for some time baffled with this difficulty, one of us (W. P. M.) found a method of circumventing it, which very often does away with the necessity of making a series of subcultures. This expedient consists in making the suspension of the culture in distilled water instead of in physiological salt solution or nutrient broth. The longer, within limits, the water is left in contact with the culture *the greater is the phagocytic* count. The favouring influence of treatment with distilled water manifests itself also in the case of pneumococci which have by subculturing become susceptible to phagocytosis. This is shown in Tables III. and V.

(*b*) A *second* difficulty presents itself in the fact that phagocytosis is restrained by an excess of microbes in the suspension employed in the phagocytic mixture. To give examples: The pooled blood of five laboratory workers was tested in phagocytic mixture with suspensions of the pneumococcus containing respectively 1800, 900, 300, and 100 millions of microbes. The phagocytic counts obtained with these four suspensions were respectively 1·01, 4·96, 3·16, and 2·28 *per cell.* In another experiment in which W. P. M.'s serum was put up with an uncounted suspension of pneumococcus and with 2-, 4-, 8-, 16- and 32- fold dilutions of that suspension, the phagocytic counts of the series of dilutions corresponded to 1; 3·1; 2·65; 1·65; 1·6; and 1·3 respectively.

TABLE III.

(*c*) A *third* difficulty presents itself in the fact that every strain of pneumococcus—and from this point of view every case of pneumonia furnishes a separate strain—gives a different amount of phagocytosis; and that the order of merit of a series of sera as determined by reference to one strain is not the same as the order of merit as determined by reference to another strain. Evidence of this is *furnished by the typical experiments set out in* Tables IV. and V.

A *fourth* difficulty presents itself in the fact that *different subcultures of one and the same* pneumococcus give, even when the suspensions employed contain exactly the same numbers of microbes, quite different amounts of phagocytosis. Differences in the composition of the culture medium here exercise a determining influence. When using cultures grown on agar made up with heated serum we obtained with all sera relatively high phagocytic counts. Cultures grown on agar made up with unheated blood gave, on the other hand, with ordinary sera a low phagocytic count, and with from pneumonia, and oftentimes of uninoculated natives who were living exposed to infection in the Witwatersrand Native Labour Association compound. Here we obtained for the pooled sera values which were, more often than not, much lower than the arithmetical mean of the component sera. A series of quite typical examples are subjoined in Table VII.:—

We are unable to furnish any satisfactory explanation of these findings. It occurred to us as a possibility that the phenomena here in question might be asociated with a negative phase, or at any rate with the presence of a pneumococcic antigen in the blood; but despite the fact that we devoted much labour to the study of the question, we were unable to satisfy ourselves on the point. far greater moment and far more urgent was us the task of replacing the method of pooling e sera which had been recognised as fallacious some better method. After a time we succeeded finding such a method. It is a procedure for the oling of a series of phagocytic mixtures.

The essential features are as follows. We take r group of bloods, a group of usually four to six oods. Using then for each blood a separate pillary pipette we make our series of phagocytic ixtures; and working as rapidly as possible we nge these side by side in separate drops on a ass slide. We then take in hand a somewhat rger and more roomy capillary pipette; inscribe a lucial mark on its stem; and then aspirate into is an equal volume of each phagocytic mixture—dividing off the mixtures in each case by a bubble of air, a minute volume of physiological salt solution (taken up from a watch-glass placed ready to hand), and another bubble of air. This done, we seal up the tip of the pipette and insert it into the opsonic incubator. After incubation the phagocytic mixtures are blown out on to a slide so as to form a common drop (the intervening drops of salt solution may if desired be discarded). Finally, after the contents of the drop have been repeatedly drawn up into and blown out from the pipette, so as to effect thorough intermixture, we make our films.

When it is desired to compare the effect of pooling after incubation with pooling before incubation, we leave behind on the slide, when filling in our first pipette, enough of our phagocytic mixtures for filling in a second. Into this second pipette we take up, as before, an equal volume of each phagocytic mixture; but we now immediately blow them out so as to form a common drop; and then, after mixing, draw them up into the pipette—obtaining in this way the equivalent of an experiment with a pooled serum.

On referring to the subjoined table and comparing columns 3 and 5, it will be seen that we obtain by pooling the phagocytic mixtures after incubation values which show an all but exact correspondence with the values obtained by averaging the phagocytic counts obtained when the constituent sera are separately tested. And it will be seen on referring to column 4 of this table and to column 3 of the foregoing table, that we obtain with phagocytic mixtures pooled before incubation just such results as are obtained with pooled sera.

Phagocyto-Bactericidal Power.

Reverting to the line of thought we were pursuing before entering upon the above excursus, we now pass on to consider yet another antibacterial attribute of the blood. We have seen that the data furnished by measurements of the pneumo-opsonic power were not sufficiently consistent from one day to another to allow of their being employed for the selection of the *optimum* dose of pneumococcus vaccine. This made us cast about for some other method of blood examination which should be competent to do what the measurement of the opsonic index had failed to do. In this way we came upon the method which is here to be described. We may, for reasons which will presently appear, designate it by the name of the "phagocyto-bactericidal method."

With regard to this method we may point out at the very outset that while it will, as it seems to us, help to illuminate the darkness which covers the mechanism of the destruction of microbes in the organism, we recognise that it would be difficult to apply on a large scale outside the four walls of a laboratory. For this reason, and because by the time that we had alighted upon the method our laboratory investigations were drawing to a close, and also because we had already obtained from the opsonic method sufficient information to allow of our now pursuing our investigations, so far as they related to prophylaxis, by the method of mass-experiments, we did not ourselves employ the phagocyto-bactericidal method for the determination of the optimum dose of vaccine.

What pointed the way to the investigation of the phagocyto-bactericidal power of the blood was the fact that we had failed to find in the films which came under close inspection in connexion with our opsonic measurements any indication of an intracellular digestion of pneumococci in the phagocytes.

It was natural to pursue these observations by making cultivation experiments, employing in these the looped pipettes with the original bactericidal technique already referred to. On actually making experiments we found, with absolute uniformity, that there does not occur in the ordinary phagocytic mixture any destruction of pneumococci, even when the microbes are left in contact with the serum and corpuscles for as long as 24 hours. It immediately suggested itself to employ the modified bactericidal technique, which permits of working with practically undiluted blood,[7] and to experiment with (*a*) unaltered blood issuing direct from the capillaries; (*b*) defibrinated blood—i.e., leucocytes and serum obtained by stirring up the clot in an ordinary blood capsule; (*c*) human and horse blood in which clotting had been deferred by the action of cold; (*d*) decalcified and recalcified bloods; (*e*) plasma separated from the unaltered blood by rapid centrifugalisation; and (*f*) the residue of corpuscles which remains over after pipetting off the plasma. We propose elsewhere to treat fully of the results of these and other experiments. We accordingly set down here only what is fundamental and what relates specifically to the problem of the natives' defective resistance against pneumococcic infection.

The following experimental results seem to us from these points of view specially deserving of attention:—

(1) We find that when blood fresh from the capillaries operates upon the pneumococcus it invariably kills quite large numbers of pneumococci. We have obtained in this way with our own bloods a destruction of pneumococci equivalent to a destruction of 600,000, and on one occasion to 1,000,000 pneumococci, by 1 c.c. of blood.

(2) In connexion with the staphylococcus—a microbe which is not destroyed either by undiluted serum, nor yet by the serum and white blood corpuscles in the ordinary phagocytic mixture—a bactericidal effect, but on a much smaller scale than that with the pneumococcus, is obtained by the operation of the unaltered blood.

(3) In experiments made by our fellow-worker, Captain S. R. Douglas, in which serum and unaltered blood were respectively brought to bear upon the tubercle bacillus, a definite bactericidal effect was obtained with the whole blood, but not with the serum. There remains, however, to be studied in connexion with the tubercle bacillus—for the results obtained with it have not been uniform—the influence exerted by the age and strain of the culture and by the length of exposure to the action of the blood.

(4) No bactericidal effect upon the pneumococcus is exerted by the plasma which has been separated by centrifugalisation from the unaltered blood. We conclude from this that the phagocytes are an essential factor in the bactericidal action of the whole blood, and that action is a phagocyto-bactericidal action.

(5) With the corpuscles and serum of defibrinated blood, and with the decalcified blood we have obtained practically no bactericidal effect. We obtained some bactericidal effect with recalcified blood. We infer from this that contact with the unaltered plasma, or possibly the chemical change associated with blood coagulation,[8] is an essential factor in the destruction of the microbes.

(6) We obtained no bactericidal effect with either human blood or horse blood which had been cooled over ice.

(7) While we obtained in a uniform manner with our own unaltered bloods a destruction of considerable numbers of pneumococci, we did not in four series of experiments carried out on uninoculated and inoculated tropical natives obtain in any instance any considerable phagocyto-bactericidal effect upon the pneumococcus.

EXCURSUS NO. II.—*On the Racial Differences between the Tropical African Native and the European with respect to the Antibacterial Effect which their Bloods exert upon the Pneumococcus.*

We have in the course of the foregoing study of the antibacterial effects exerted by the blood upon the pneumococcus made frequent reference to the fact that the antibacterial power of the native bloods was less than that of our own bloods. Seeing that we have perhaps here the explanation of that high incidence-rate and great fatality of pneumonia, pneumonic cerebro-spinal meningitis, and other pneumococcic infections among African natives congregated upon the Rand and elsewhere in labour camps and compounds, it will perhaps be of interest to gather together the results of the observations which we made in the course of our work on the differences between native and European bloods.

We found in our study of the bactericidal and growth-inhibiting powers of the serum only slight indications of a difference between the sera of the African native and the European. If there was such a difference the advantage lay with the European.

In connexion with our measurements of the opsonic power of the blood, there was no longer any possibility of doubt. Here, as will be seen from the results collected into the subjoined table, very distinct differences emerged.

TABLE IX.—*Showing the Pneumo-opsonic Indices obtained by Dividing in Each Case the Arithmetical Mean of the Phagocytic Counts of a Group of Europeans (Laboratory Workers), with the Average Phagocytic Count* of a Group of Uninoculated Tropical African Natives.*

[7] It may be explained that the fact of the blood clotting in the capillary stem is, from the point of view of that technique, perfectly indifferent.

* This count was obtained by pooling, in accordance with the [illegible] exudation clots in the alveoli of the [illegible] other hand, that enormous numbers of pneumococci are killed off in that exudation.

The findings which are set forth in this table and its teaching may be summarised as follows:—With eight of the 13 strains of pneumococcus which were tested, the sera of the uninoculated tropical natives (it will be remembered that a certain number of infected natives must have been included among our uninoculated) gave opsonic indices of less than one, and generally of much less than one. With the remaining five strains the sera of the uninoculated tropical natives gave indices of one or a little above or below one.

The strains which brought out differences as between tropical natives and Europeans were in all cases virulent strains, in the sense that when originally isolated they failed to give phagocytosis; and could only, by repeated cultivation on artificial media and suspension in water, be brought into a condition to give phagocytosis. Moreover—and the significance of this will not be missed—when these strains began to give phagocytosis they in every case gave it, at first, only with European sera. After a time they began gradually to give it also with the sera of uninoculated tropical natives. The fact that strain No. 92 continued for a long time to differentiate sharply between native and European bloods is, we think, due to our having nearly always grown this strain on agar made up with unheated blood.

With regard to the strains of pneumococcus which failed to bring out differences between native and European bloods these were presumably non-virulent strains. They were, at any rate, either strains which gave phagocytosis immediately on isolation from the patient or strains which had been subcultured without special precautions for a long time outside the body.

Compressing all the above into a sentence, we may say that the teaching of the table resolves self into this: that where in connexion with the eumococcus a difficult task is set to the blood, he native is far behind the European, but that where an easy task is set he draws up level.

Having considered the facts which relate to the uninoculated native, we have now to carry our thoughts back to those which relate to the native who is making immunising response to inoculation or auto-inoculation, and to ask ourselves what is the precise significance for the problem here under discussion of the observation that it is only exceptionally that the opsonic index of the native who is making immunising response comes up to the arithmetical mean of the pneumo-opsonic indices of the Europeans who served as controls in these measurements. The full significance of this fact comes home to us only when we realise that it is, not so much the original content of a patient's blood in protective substances, as his capacity for generating these in response to microbic invasion which gives the measure of his power of combating infection. Once this principle has been grasped it becomes clear that there is furnished to us, in the comparison between the opsonic power of the normal white man and that of the native who is making active immunising response, a better measure of the native's defect of resistance than is afforded by the comparison between the opsonic power of the normal white man and that of the normal native.

But there will perhaps here suggest itself the question as to whether there is really anything to indicate that the correlation between the native's relatively low opsonic index and his relatively high susceptibility to pneumococcus infections is not an accidental association. A comparison between the native's opsonic power to staphylococcus with that of the white man would go far to settle this point. For by common consent the native is a good "subject for operation"—probably a better subject than the European. This is as much as to say that the native offers good resistance to the common microbes of wounds—a state of things which ought, if there be a causal correlation between the opsonic power of the blood and the power of fighting a microbic infection, to go together with a satisfactory opsonic index. We made this almost critical investigation, repeating it four times, with the results which are set forth in the subjoined table:—

TABLE X.—*Showing the Results of a Comparison between the Staphylo-opsonic Power of Europeans and Tropical African Natives.*

[*] It will be remembered that it has been shown in Excursus No. 1 *supra*, that when dealing with normal bloods the phagocytic count of the pooled serum is equivalent to that of the highest of the constituent sera.

[†] This and the following groups consisted of 4 to 6 natives.

The above results clearly lend very strong confirmation to the view that the native's deficiency in pneumo-opsonic power does stand in some causal relation with his low resisting power to pneumococcic infections.

Finally, it would be difficult to doubt that we have in the defect of pneumo-phagocyto-bactericidal power to which attention was called above a native character which stands in direct causal relation to the ravages which the pneumococcus makes among them.

(To be concluded.)

ROYAL ALEXANDRA HOSPITAL, BRIGHTON.—An interesting ceremony recently took place at the Royal Alexandra Hospital for Sick Children, Brighton, when the gift of a complete X ray apparatus was formally received by the committee, and a tablet was unveiled recording "The Louise Sassoon Electrical and X Ray Department." The opening ceremony was performed by Dr. E. Hobhouse in the presence of a numerous company, and a demonstration was given by Mr. W. Barrington Prowse, honorary skiagraphist of the hospital.

A Clinical Lecture

ON

SOME LATE MANIFESTATIONS OF INHERITED SYPHILIS.

Delivered at the London Hospital

BY J. H. SEQUEIRA, M.D. LOND., F.R.C.P. LOND., F.R.C.S. ENG.,

PHYSICIAN TO THE SKIN DEPARTMENT AND LECTURER ON DERMATOLOGY AT THE HOSPITAL.

GENTLEMEN,—I propose to direct your attention in this lecture to a type of eruption occurring in inherited syphilis which is of the utmost importance for the following reasons: it is frequently mistaken for another disease—viz., lupus vulgaris—and leads to terrible deformity which is only paralleled by certain advanced cases of rodent ulcer of the face.

CASE 1.—The little girl now shown (Fig. 1) is 16 years of age, though her aspect would suggest that she was about 12. She was sent to the London Hospital for treatment by the Finsen light, it being believed that her condition was common lupus. She gave the following history. Five or six years ago she received a severe blow upon the nose from the fall of an iron pipe. The skin was not broken, but some months later an ulceration started at the inner canthus of the left eye. Under treatment this healed up. A little later the nose became much swollen, and an operation was done about three years ago for the removal of *dead bone*. From that time onwards pieces of dead bone have been removed from time to time. For several months the patient was an inmate of a provincial hospital, and later while attending as an out-patient she had some applications of the X rays, with the result that a portion of the ulceration at the periphery healed. About 12 months ago an ulcer appeared upon the right arm. Nine months ago a similar destructive ulceration appeared upon the forehead.

Family history.—The father is alive and well, the mother is dead. The patient has one brother, aged 36, and sisters aged 31, 27, and 20, all apparently well. The youngest child of the family, a boy aged 15, has had "sores" on the legs. Six other children are said to have died from "fits."

Condition on admission.—You will see that there has been extensive destruction of the nose, of which only a portion of the right ala remains. I especially call your attention to the fact that not only has the cartilage disappeared but also a large part of the bone both of the sides of the nose and of the septum. When the girl was admitted the cavity was in a very foul condition, the ulcerated areas being covered with pale greyish sloughs and muco-pus. You will also notice that there is a roughly triangular ulcer on the forehead extending from the eyebrows and root of the nose to beyond the hairy margin of the scalp. This was very dirty and was exuding a dirty pus. There are superficial scars upon each cheek, and on them are a few telangiectases such as one meets with in cases that have been submitted to the X rays. The right forearm is immovably flexed upon the arm, at about a right angle. Around the elbow and on the inner aspect of the limb are large irregular ulcers with raised margins, the bases being covered with dirty sloughs. (Fig. 2.)

The development of the girl is very poor. She is small for her age, and has a childish appearance. There is no enlargement of the liver or spleen. The eyes are unaffected, and the hearing is normal. There are no Hutchinson teeth. The Wassermann reaction is positive.

On Sept. 25th, 1913, she received an intravenous injection of neosalvarsan, 0·3 gramme, and was also put on a mixture containing potassium iodide. Four days later the ulceration on the forehead had very much improved and the ulcers on the arm were cleaner. On the 30th she received a second injection of neosalvarsan, 0·45 gramme, also intravenously. The improvement was remarkable, and on Oct. 2nd the ulcer on the forehead had almost healed.[1] A radiograph taken by Mr. S. Gilbert Scott showed that there had been severe damage to the elbow-joint, a damage which suggested severe trauma or advanced tuberculosis.

CASE 2.—This little girl is now 16 years of age, though she looks like a child of 11 or 12. She came first under my care in October, 1908, and I am showing the photograph of her condition then. (Fig. 3.) Her history is interesting. She had been attending at a dispensary for a long time for supposed tuberculous peritonitis, and had had the usual treatment. *Three weeks* before her admission to the hospital the nose began to swell, and rapidly ulcerated, the ulceration extending on to the upper lip. She was sent to me as a case of lupus for the Finsen light treatment.

Condition on June 16th, 1908.—There was an extensive ulceration which had destroyed the greater part of the nose. This ulcer had an irregular outline and its base was covered with greyish sloughs and dirty muco-purulent discharge. Extending from the under surface of the nose to the margin of the lip was another deep ulcer with raised margins and an irregular sloughy base. There was also a dirty ragged hole in the hard palate in the middle line.

The *family history* was instructive. There had been ten children, and six of these were alive. One infant was born dead, and three died within the first few months after birth. Three of the living children had had infantile eruptions, almost certainly syphilitic, and one had an ulcer in the roof of the mouth when 3 years of age. The mother attends here, and I may say in passing that she has a positive Wassermann reaction.

The little girl, in addition to the lesions on the nose, palate, and lip, had an enormously swollen abdomen. This was found to be due in part to ascites, but chiefly to an enlarged liver, which extended to the umbilicus, and a spleen which reached as low as the left iliac crest. These have now resumed their normal size.

The child was admitted into the ward and was treated by mercurial inunction (this was in 1908). In three weeks the ulcers on the nose and the upper lip had healed, but unfortunately left disastrous scars. The hole in the palate was a long time healing, as several pieces of necrosed bone came away during the year after she had been in hospital. There is now a large cavity, which at some time later may be closed by an obturator. The girl shows two characteristic Hutchinson teeth, but she is not deaf, and there is no interstitial keratitis.

CASE 3.—I am showing also photographs of another case, that of a boy aged 15, under my care

---

[1] In the ensuing fortnight all the ulcers had healed with the exception of a small area on the inner side of the right forearm. This has since cicatrised.

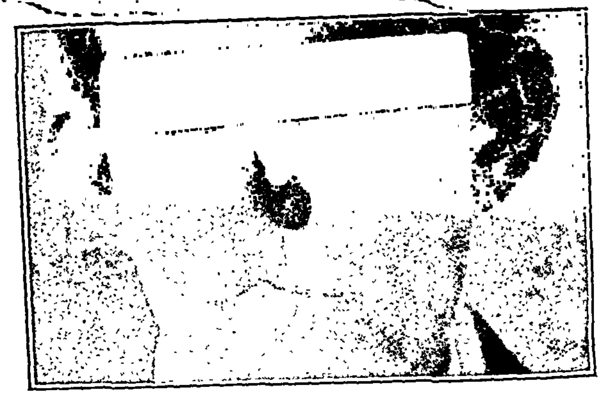

FIG. 6.—Complete destruction of nose and palate.

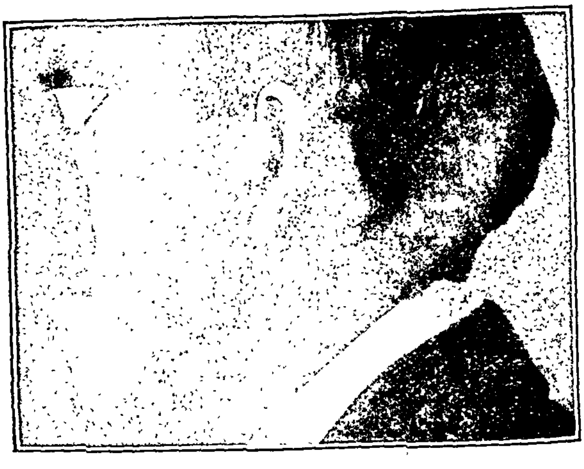

FIG. 7.—Profile of patient shown in Fig. 6.

in 1908. He was the eldest of a family of five, his four sisters being quite well. The disease began on the right cheek with the formation of a "lump" which "burst" and discharged. Eventually the ulceration spread over the cheek as high as the outer canthus and lower lid and across to the middle line of the nose. It was scraped, and the boy had medicine; under this treatment the ulcer healed. *Three months* before admission a sore appeared upon the upper lip and gradually spread; *one month* before admission the lower lip began to swell and the swelling ruptured to form an ulcer which rapidly spread. (Fig. 4.)

On admission there was extensive scarring of the right cheek leading to ectropion, and the whole of the right ala nasi had been destroyed. The extent of the ulceration around the mouth is shown in the figure. Once more let me impress the point that this destruction of the upper lip had taken place in three months, and that on the lower lip in one month. There were characteristic Hutchinson teeth well seen in the figure. There was no interstitial keratitis and the hearing was normal. The abdominal organs presented no sign of disease. The bones were also unaffected. This case was also sent to the hospital with the diagnosis of lupus vulgaris.

The boy was treated by mercurial inunction, and 5-grain doses of potassium iodide. The ulcers were fomented and dressed with an ointment of peroxide of zinc. The inunction was continued for 16 days, when the gums were slightly affected. The ulcers had entirely healed in one month. The boy, I may add, gave a negative Calmette reaction to tuberculin.

CASE 4.—This is the photograph of another case of the same type. The patient was a girl, 16 years of age. She also showed the infantilism which I have mentioned in the first two cases. The eruption began when she was 13 years old, on the side of the nose, and gradually spread. She had attended a throat hospital, where an operation was performed. Six weeks before her admission an ulcer developed upon the left side of the upper lip, and about the same time a swelling appeared at the outer part of the right eyebrow, and this swelling subsequently broke down into an ulcer.

On admission the whole of the ala nasi on each side and the lower part of the nose had been destroyed, and the area was covered with dirty crusts of dried pus. There were a similar ulcer covered with crust at the left side of the upper lip and a large brownish crust, from the side of which pus was exuding, at the outer side of the right eyebrow. (Fig. 5.) There was a ragged hole in the hard palate. The tonsils, uvula, and the whole of the soft palate had disappeared. The upper incisor teeth were of the Hutchinson type. There were no visceral complications, but there was interstitial keratitis in both eyes. The hearing was not affected. Under mercurial inunction and iodides the ulceration healed completely in 21 days. The lesions were dressed with iodoform ointment. The girl has been provided with a false nose, and this has improved her appearance remarkably. This patient was also sent to the Finsen light department as a case of lupus vulgaris.

CASE 5.—The last patient I have to present is one some of you may remember as being under treatment last year. He was admitted on Sept. 24th, 1912, and illustrates the extent of the deformity seen in some of these untreated cases. The history was that when the patient was 8 years of age he had a blow on the nose, and that 12 months later a "lump" which had formed "broke." Ultimately a huge cavity developed, the whole of the interior of the nose and the hard palate coming away with the formation of hard crusts. There was also an ulceration of the upper lip, the scars of which are well seen in the photographs. (Figs. 6 and 7.) He was sent to me as a case of lupus, there being still some discharge from the interior of the nose. The Wassermann reaction was positive. The patient had two injections of neosalvarsan, which speedily healed up an area of ulceration in the remnant of the nasal cavity.

Mr. F. M. Farmer kindly saw the patient for me with a view to providing some mechanical apparatus which could be made to supply the place of the palate, but this was impossible. A false nose and lip to replace the areas destroyed were the only possible method of improving the patient's condition. This has been provided by Mr. Brook, of Halifax, who had helped us in similar cases.

The points I wish specially to bring out in these cases are: (1) The patients are from 8 to 15 years of age. (2) A history of injury is common. (3) The *rapidity of the destruction is quite unlike* that met with in lupus vulgaris. Syphilis produced destruction in a few weeks which the tuberculous process takes years to accomplish. (4) The destruction of bone. I have seen many cases of lupus, but lupus does not destroy bone. It eats away cartilage but it does not cause necrosis of bone. The fact that the patient has noticed the presence of dead bone in the discharge from a nasal or palate ulceration is valuable evidence in favour of syphilis. Lastly, I would comment upon the remarkable response of these destructive lesions to antisyphilitic treatment, whether salvarsan, neosalvarsan, or mercury. In any case of doubt I would urge you, in view of the rapidity of the destruction, not even to wait for the Wasserman reaction, but to start antisyphilitic treatment at once. You will do no harm if the patient is tuberculous; you may do irreparable harm by waiting even for a few days if it is syphilitic.

GLYCOSURIA IN THE COURSE OF AFFECTIONS OF THE LIVER: HEPATIC DIABETES.

BY MARCEL LABBÉ,
PROFESSEUR AGRÉGÉ AT THE UNIVERSITY OF PARIS, PHYSICIAN TO LA CHARITÉ;
AND
AMBROISE BOUCHAGE, M.D. PARIS.

SINCE Claude Bernard's well-known experiments no one doubts that the liver plays an essential rôle in glycogenesis. Claude Bernard went so far as to say that the cause of diabetes was to be localised in the liver. After him many writers have said that the cause of diabetes, or at any rate of a certain class, was due to hepatic disorders. Lécorché held the opinion that this affection was due to an *exaggeration* of the hepatic functions. Seegen, Pavy, and Schiff admitted the existence of a hepatogenous diabetes. Glénard has laid great stress upon the lesions found in the liver in diabetes, and has attributed to them the prominent rôle in the causation of the disease. Lately Gilbert was of the opinion that there were two types of diabetes caused by functional hepatic disorders: one due to *hyperhepaty*, the other to *hypohepaty*. However, some writers, having frequently found the liver untouched in diabetics, do not attribute to it such a preponderant rôle in the causation of diabetes. This being so, we thought it would be of some interest again to raise the question from a clinical point of view and try to determine the relations between hepatic disorders and diabetes.

We will consider the question under five headings: 1. The glycosurias that occur *during the course* of hepatic lesions. 2. The hepatic congestions in overfed people. 3. The post-infectious or toxic hepatic disorders. 4. The "diabète sans dénutrition" with enlarged liver of the overfed. 5. The hepato-pancreatic cirrhosis with severe diabetes.

1. *Glycosurias accompanying hepatic lesions.*—In cirrhosis and other lesions of the liver (cancer, cardiac liver) the glyco-regulator function is generally disturbed, but not sufficiently to cause what may be called diabetes. Most frequently the alimentary glycosuria test has to be resorted to in order to show the existing glyco-regulator trouble. Sometimes, in more advanced troubles, glycosuria is spontaneous, but intermittent, moderate in amount, and unaccompanied by other symptoms of hyperglycæmia. This form of glycosuria is more often seen at the beginning of cirrhosis of the liver than at a later stage. Several of our cases demonstrate the fact.

2. *Hepatic congestions in the overfed.*—People indulging in overfeeding, especially with meat, sometimes develop a glycosuria accompanied by hepatic congestion and disturbances in the functions of the liver. This type may be illustrated by the following cases.

CASE 1.—The patient, 29 years of age, had been losing flesh and strength for a year; he was suffering from lumbar pains, and he sought medical advice because he was afraid of phthisis. His complexion was subicteric, the tongue was dirty, and the stomach was dilated. He passed two soft motions a day. The liver was enlarged, measuring 14 centimetres in the mammary line; other organs sound. The urine was scanty (1 litre) and contained a large amount of total nitrogen ($18\frac{1}{2}$ grammes) and of urea (35 grammes). There was a large excess of urobilin and indican present, and some traces of biliary pigments. Six grammes of glucose were found. The patient confessed that he ate too much meat. This was to be suspected from the analysis of his urine. He was placed on a lacto-vegetarian diet and on a Vichy water cure. In July he felt better. He passed 3 litres of urine per day, containing 7·8 grammes of total nitrogen, 15 grammes of urea, and small quantities of urobilin and indican. The glycosuria ceased; the liver was not so big and measured only 12 centimetres. During September the improvement was maintained. He had put on 2 kilogrammes in weight and there was no glycosuria. In December he was better. The weight had increased by 5 kilogrammes. The liver was smaller and measured only 11 centimetres. Later on the conditions were much the same. If the patient indulged in any alimentary excess, the hepatic disorders reappeared, the liver enlarged again, urobilinuria and glycosuria reappeared, and traces of albumin could be detected in the urine. These symptoms disappeared readily with a lacto-vegetarian diet.

CASE 2.—The patient, 34 years of age, after presenting some signs of tuberculosis in the lungs in 1900, was sent to the South of France for a rest, and there was submitted to a cure of superalimentation. Besides the ordinary diet he used to take every day 12 raw eggs, 700–800 grammes of raw meat, and to drink two small claret-glassfuls of cod-liver oil Under the influence of this diet he improved and increased rapidly in weight.

In 1902 a fresh outbreak of tuberculosis forced him to overfeed again, since which he had eaten a good deal of meat At the beginning of 1907 he had symptoms of muco membranous enteritis. There were very severe pains in the upper part of the ascending colon that suggested appendicitis, and the advisability of an operation was considered. The urine was examined and glycosuria was occasionally found. The patient was then seen by one of us. The tongue was coated, there was a bitter taste in the mouth, and the breath was foul. Stomach normal; liver slightly enlarged. The urine contained some reddish-brown biliary pigment. The lesions in the lungs were apparently completely cured. A diagnosis of gastro-enteritis with congestion of the liver caused by overfeeding was made. A mixed light diet caused immediate improvement.

CASE 3.—The patient, 48 years of age, of sedentary occupation, was a heavy eater, and drank a considerable amount. His general health had been good. For some time he had been complaining of a dull sensation of pain in the lumbar region and had had œdema in his ankles. Examination of the urine revealed a slight amount of glycosuria and the existence of a reddish-brown biliary pigment. He was a rather stout man, and looked older than his age. His complexion was subicteric, and some signs of arterial hypertension were found. The liver was enlarged. A reduction in the amount of the diet quickly diminished the glycosuria. Under the influence of a lacto-vegetarian diet, exercise, and a Vichy water cure he lost some weight and felt more supple and fit. The glycosuria had disappeared in five weeks. The liver had resumed the normal size, and the arterial tension had also fallen.

The story was identical in all these cases. A subject indulges in overfeeding, especially with meat. Sooner or later supervenes a congestion of the liver with functional hepatic disturbances and glycosuria. The patient thinks he is diabetic. In these cases the glycosuria is moderate in amount and unaccompanied by the chief symptoms of hyperglycæmia. It is noteworthy that this glycosuria disappears at the same time as the other hepatic disorders under the influence of a lacto-vegetarian diet and a Vichy water cure—that is to say, under a diet and treatment that give the liver rest and excite the functions of the hepatic cell.

To treat this class of glycosurias with a meat diet and reduction in the amount of the carbohydrates absorbed would be simply a mistake. Far from curing the existing glycosuria, this diet, on the contrary, would increase it.

Such cases should not be called diabetes. Nevertheless, they are on the borderland of the disease, and if the patients had continued to overfeed perhaps some of them would later have become true diabetics.

3. *Post-infectious or toxic hepatic disorders.*—After acute infectious diseases a complexus of hepatic disorders accompanied with glycosuria that reminds one of diabetes is sometimes seen.

CASE 1.—The patient, 32 years of age, was suffering from suppurative tonsillitis with fever. At the outset of the symptoms she had epistaxis and vomited bile. In the last stage of the disease slight glycosuria accompanied with a large amount of urobilin, bile pigments, and ammonia was seen. For several days the urine contained reducing substances in large quantity. These symptoms then disappeared.

CASE 2.—The patient, 56 years of age, was asthmatic and dyspeptic. He ate much sugar. He was suffering from measles. During the course of that disease he lost flesh rapidly, and in the urine 5 grammes of glucose, 10 centigrammes of albumin, and some urobilin were found. The liver was slightly enlarged and tender on palpation He was afraid of diabetes, though presenting no other symptom of hyperglycæmia besides the glycosuria A mild lacto-vegetarian diet caused the glycosuria to disappear.

These facts can be explained as follows. An affection attacks the various functions of the liver, especially the glyco-regulator function. This will cause a glycosuria which as a rule is moderate in amount. There is here a slightly more advanced stage of what is seen in the course of acute infectious diseases in which the alimentary glycosuria test usually shows the existence of glyco-regulator trouble.

Between a simple alimentary glycosuria and a *post-infectious diabetes a series of transitory stages* exist. It will easily be conceived that with a subject otherwise predisposed or already slightly affected a fresh infection will determine a true diabetes. One of us has given some illustrations of this fact.

4. "*Diabète sans dénutrition" with an enlarged liver in the overfed.*—This "diabète sans dénutrition" supervenes in those who are in the habit of overfeeding themselves, and is often accompanied with an enlarged liver and disturbances in the functions of that organ.

CASE 1.—The patient, 45 years of age, was a very heavy eater and took no exercise. The abdomen was large and fat. He had suffered from pains in the joints, apparently of a gouty nature, and had had renal colic. He had been a diabetic for several years. On an average about 100 grammes of sugar were now found in the urine. From time to time he had an attack of post-prandial biliary diarrhœa. The liver was slightly enlarged. The patient was of subicteric complexion. A diet with reduction of carbohydrates caused a rapid disappearance of the glycosuria and produced a slight loss of weight. At the same time the digestive troubles ceased.

CASE 2.—The patient, 51 years old, lived a sedentary life, ate a great deal, and drank one litre of wine a day. He was very obese and had weighed as much as 104 kilogrammes, but now he weighed 96 kilogrammes. In 1901, *while suffering from furunculosis, he had an attack of* glycosuria, passing 69 grammes of sugar a day. He was put on a special *régime*, and after a month's treatment he quite recovered. Later, however, the disease again manifested itself, and in spite of a mineral water cure he passed between 5 and 15 grammes of sugar a day. Digestion was slow. The liver was hypertrophied and reached below the costal margin. The urine indicated an overfed condition and [illegible] 1·10 grammes of uric acid; and traces of albumin. On [illegible] glycosuria and albuminuria quickly disappeared and the patient lost slightly in weight.

CASE 3.—The patient, 49 years old, ate and drank a great deal. He was obese and suffered from diabetes. When 39 years old, on being examined for life insurance, he was *found to be passing sugar in the urine. This disappeared* rapidly. When 46 years old, on being again examined, the amount of sugar in the urine was found to be 30 grammes a day, and in spite of careful diet the glycosuria persisted and varied between 30 and 60 grammes a day. The patient was obese, easily tired and out of breath, and complained of his mouth being dry. He went to stool twice daily, the motions being soft. The liver was enlarged, the anterior inferior border reaching 5 centimetres below the costal margin. The patient's complexion was subicteric. He suffered from hæmorrhoids, and the urine contained 41 grammes of glucose, together with urobilin and albumin. Being put on a reduced carbohydrate diet, the glycosuria disappeared after four days, the albumin was reduced to a trace, the patient lost a little weight, and his general condition was much improved. Subsequently the condition remained stationary. The liver was still hard and enlarged. The urine contained traces of albumin and urobilin. However, directly he altered or increased his diet a glycosuria amounting to several grammes made its appearance.

5. *Hepato-pancreatic cirrhosis with severe diabetes.*—Lastly, there is a group of diabetes connected with hepato-pancreatic cirrhosis. The *diabète bronzé* is of this class. Here the glycosuria is severe and accompanied by nitrogenous waste and often by acidosis; the hepatic cirrhosis is well marked; the cirrhosis of the pancreas is revealed by more or less marked signs of pancreatic insufficiency. Hence, in these cases there is a simultaneous evolution of a severe glycosuria and of a lesion of the liver and pancreas, but it is impossible to decide whether the liver or pancreas plays the first rôle in the pathology of the diabetes.

Such are the facts, and they show that in the course of hepatic affections one may observe every degree of glyco-regulator disturbance—from the simple alimentary glycosuria induced by the Colrat's test to the most characterised diabetes.

The boundary between diabetic glycosuria and non-diabetic glycosuria is difficult to determine. A hardly appreciable transition leads from one to the other. Achard and Weil have shown that a certain class of arthritic people who have later on become diabetics began by presenting an alimentary glycosuria. Reciprocally, we have seen true diabetics who, after presenting the complete hyperglycæmic syndrome, when put on a well-regulated diet have only had a very small amount of glycosuria, and finally no glycosuria at all, except when it has been induced by an injection of glucose.

Is there any necessity to group some of those facts under the name of hepatic diabetes? By all means, for it is always possible to argue about that interpretation, since glycosuria is a sign of both hepatic insufficiency and pancreatic, thyroid gland, or nervous insufficiency. Besides, it seems very difficult indeed to say that of all the organs of the glyco-regulator system the liver is the only one attacked. However, it appears to us that the name of hepatic diabetes should be reserved for a certain class of cases in which the alteration of the liver is manifest.

This hepatic diabetes supervenes, as a rule, in heavy eaters. It is preceded often by obesity, sometimes by gout or renal lithiasis. It is a mild diabetes without any nitrogenous waste, corresponding to the classical type of the *diabète gras* or *arthritique*. It is accompanied by the usual manifestations of alteration of the liver: hypertrophy of the organ, subicteric complexion, and the presence in the urine of excess of biliary pigments, of brownish-red pigment, of urobilin, ammonia, and the amino-acids. The nitrogen index is low. Again, the patients may sometimes have hæmorrhages and disturbances due to blood coagulation.

The cause of this hepatic diabetes may be a general infection that attacks the liver, an intoxication such as by alcohol, which has an affinity for the liver cells. More often, according to our observations, it is due to overfeeding, especially on meat.

The glyco-regulator disturbance, as a rule benign, may be cured if the anatomical and functional integrity of the liver can be restored. This will show how important is the treatment of hepatic diabetes.

The treatment is chiefly directed to the liver, the basis being mineral water cure such as by the waters of Vichy, Brides, Carlsbad; hepatic opotherapy; lacto-vegetarian *régime*. While avoiding excess of carbohydrates, it is important to reduce the quantity of meat ingested, the chief cause of the trouble.

MAJOR R. J. BLACKHAM, R.A.M.C., honorary surgeon to the Viceroy of India, who is the Assistant Commissioner of the St. John Ambulance Brigade in India, was the recipient recently of an address of congratulation from the Bombay Corps of the brigade on his being created C.I.E. by the King. The address was enclosed in a beautiful and valuable silver casket.

were considerably diseased I excised it, after satisfying myself that the common duct was free. An enlarged gland which lay immediately below the neck of the gall-bladder was also removed. Neither in this nor in the gall-bladder was there any sign of growth. Some caseous nodules were found in the gland, but no giant cells. I put a ligature around the cystic duct, which was quite small, and closed the wound with a drain in the space formerly occupied by the gall-bladder.

On Oct. 31st it was noticed that there was a little bile escaping from the drainage-tube and that the patient was jaundiced; her stools were clay-coloured and the urine contained bile. The discharge of bile from the wound became very free, and the jaundice which was complete continued. I was at a loss to explain this unusual combination of symptoms and to connect it with my operation, unless I had left behind a stone in one of the hepatic ducts. So on Nov. 18th I reopened the wound and found the cut end of the cystic duct patent, and bile flowing freely from it. A probe passed easily into each hepatic duct, but I failed to detect a stone in either of them. I could not pass a probe along the common duct, but I could not detect any thickening or block in the duct in any part of its course.

Amid much that was uncertain there was one undoubted fact—that the bile was flowing freely from the end of the cystic duct—so I determined to deal with this by uniting the end of the duct to the duodenum. There was less than half an inch of the cystic duct left, I therefore did not enlarge its orifice by slitting up the duct, but making a tiny incision through the coats of the duodenum I united the cut end of the duct to it by a double row of sutures. The wound in the abdominal wall was then closed above and below a drain. For a few days there was a slight escape of bile; this soon stopped, and the wound healed soundly. On Nov. 20th the jaundice was noticed to be distinctly less, and a motion passed on Nov. 21st was dark brown in colour. From this time the jaundice rapidly lessened, the motions continued of a normal colour, and the patient left the hospital quite convalescent on Dec. 12th.

The interest of this case lies in the fact that a patient who for years had had gall-stones, but without jaundice, developed jaundice immediately after the removal of the gall-stones and of the gall-bladder, and that the jaundice was unrelieved by the free escape of bile from the divided cystic duct. It is clear that something occurred at the operation which produced an obstruction or obliteration of the common duct. This was not the displacement of a stone from the cystic duct into the common duct, for not only was no stone found at the second operation, but the cystic duct was of its normal size—just admitting a probe—and had evidently never been distended by the passage of a stone large enough to block the common duct. In this respect the case reminds me of a patient upon whom I operated three years ago. She had a cholecystotomy done by another surgeon some years previously. I was called to see her for recurring attacks of jaundice with fever and acute epigastric pain. Expecting to find a stone in the common duct, I operated and found dense adhesions in the midst of which I opened a dilated common duct; this was stenosed lower down, but I was able to trace the duct through the adhesions and restore the continuity of its two portions.

But far more interesting than the blocking of the common duct as a sequel to cholecystectomy is the association of deep jaundice and dark bile-loaded urine with free escape of bile from an external fistula. I can offer no satisfactory explanation of this, nor can I explain how turning the bile again into the duodenum sufficed to remove a jaundice which was not benefited by its external escape. I was greatly relieved to find that my second operation was successful in spite of any adequate explanation.

Queen Anne-street, W.

TUBERCULOUS RHEUMATISM.[1]

BY NATHAN RAW, M.D. DURH., F.R.C.S. EDIN.,
M.R.C.P. LOND.,
VISITING PHYSICIAN, MILL ROAD INFIRMARY, LIVERPOOL.

TUBERCULOUS rheumatism was first described by Poncet, of Lyons, and other French physicians, such as Bérard, Maillant, Bezançon, and Griffon, have reported cases from their own researches, but so far British physicians have not described the condition in detail. The articular lesions in infective diseases, such as gonorrhœa, dysentery, syphilis, pneumonia, &c., are quite different from the pseudo-rheumatic arthritic lesions observed in some forms of tuberculosis.

From an observation of over 6000 cases of pulmonary tuberculosis under my care in hospital and elsewhere, I have not met with a single case of tuberculous rheumatism—at least, it was not recognised as such; and although it is very common to see cases of tuberculous arthritis attacking one or perhaps more joints, it is most rare to meet with a multiple arthritis of the smaller joints in the hands, fingers, wrists, and ankles in the course of tuberculosis.

The subject of this paper is a young lady, aged 19, of healthy parents. She has several sisters, all of whom are healthy. I am told that she was always, as a child, very fond of milk, and drank large quantities. At the age of 13 she first developed tuberculous glands in the left side of the neck. These gradually spread down to the clavicle, into the submaxillary regions, and to the right side. The infection was slowly progressive, until both sides of the neck were much swollen and very painful. Her general health became seriously affected and she lost weight rapidly. Every remedy was adopted, but nothing seemed to check the infection. At last, five years after the first onset, the glands in the original focus showed signs of breaking down, and it was decided to open and remove the contents of all the suppurating glands. This was done by Mr. W. Thelwall Thomas, but it was impossible to remove any glands, so firmly were they fixed to everything in the neck. A month after the operation the patient developed a painless, rapid effusion into the right wrist-joint, followed in a week by a similar condition in the left wrist, and followed again by swelling of all the metacarpo-phalangeal joints of both hands. There was very little pain, but the temperature was high, 102° F. at night and 99° in the morning for 10 days. Salicylate of soda had no effect whatever either on the temperature or joints. The right wrist was aspirated and half an ounce of fluid removed. Very careful cytological examinations were made in order to detect tubercle bacilli, but none could be demonstrated.

---

[1] A paper read before the Medical Section of the Royal Society of Medicine on Dec. 16th, 1913.

I injected the fluid into a guinea-pig, and also into a rabbit. The guinea-pig developed tuberculosis in four weeks, and showed a progressive tuberculosis extending to all the organs. Cultures were made from the spleen of the guinea-pig on Dorset's egg medium, and a growth corresponding to bovine tuberculosis obtained. The rabbit also developed a tuberculosis, although of not so progressive and severe type as the guinea-pig, and similar cultures were made from the spleen and liver of the rabbit. These cultures also showed the bovine characteristics.

An emulsion was made from the contents of one of the tuberculous neck glands and injected into a guinea-pig and also into a rabbit. Both animals developed in seven weeks a generalised tuberculosis, and cultures made from their organs were typically bovine in appearance. The stained tubercle bacilli showed nothing of a distinctive character.

It was clear that we were dealing with a primary infection of the neck glands with the bovine bacillus, probably conveyed through milk and absorbed from the tonsils and pharynx. The secondary arthritic infection was evidently through the blood stream. The von Pirquet reaction was most violent. There was no affection of the lungs or pleuræ.

Six weeks after the onset of joint symptoms the skin of the legs and feet became red, swollen, and brawny, and numerous bullæ appeared which soon ruptured, discharging greenish pus. Some of these appeared on the arms; after healing a dark brown stain was left on the skin, which still remains.

On the subsidence of the acute symptoms I commenced a course of tuberculin T.R. (human) in very small doses, to commence with 0·0001 mgm. The injections were given weekly in increasing strengths to a maximum dose of 0·01 mgm., and I am glad to say with most welcome result. The glands have subsided to half their previous size, whilst the joints have become smaller and more movable, although they are still stiff, but painless. The local reaction of the tuberculin at the site of injection is very marked and persists up to the present time. We can only hope that further progress will be made, as she is not yet by any means out of danger.

Examination of the fluid from the joints revealed an excess of lymphocytes, which is, of course, in favour of tuberculosis as opposed to polymorphonuclear leucocytosis, which occurs in true rheumatism.

I have only seen three cases of this rare condition. The first was in Washington, America, in 1908, and occurred in a boy, aged 14, who was suffering from tuberculous neck glands with secondary pseudo-rheumatism in both hands and wrists. His joint symptoms entirely passed off after the glands were removed and a course of tuberculin administered. The second case I saw in Berlin this year at the Rudolph Virchow Hospital, and occurred in a girl, aged 17, suffering from tuberculosis of neck glands and lupus. The third case I have just described.

It is of interest to note that these three cases were all secondary to a primary tuberculous focus in the neck glands, which is, in my opinion, almost always caused by the bovine bacillus, and I can find no record of tuberculous rheumatism occurring in the course of pulmonary tuberculosis which is most frequently the result of infection by the human bacillus. It would seem, therefore, that the bovine bacillus is much more likely to find its way into joints, and also into the blood stream, than the human bacillus, which is generally limited in its action to the lungs, larynx, and intestines.

Professor Dieulafoy divides tuberculous rheumatism into two divisions: (1) primary, and (2) secondary. He mentions a case of recovery from a primary infection, but does not record any case occurring in the course of, or preceding, pulmonary disease. Bentz, however, records two cases in which the initial lesions, Pott's disease and osteitis of the tibia, remained active, while the joint troubles disappeared without ending in definite articular tuberculosis.

Liverpool.

BULLET WOUND OF THE SPINE:

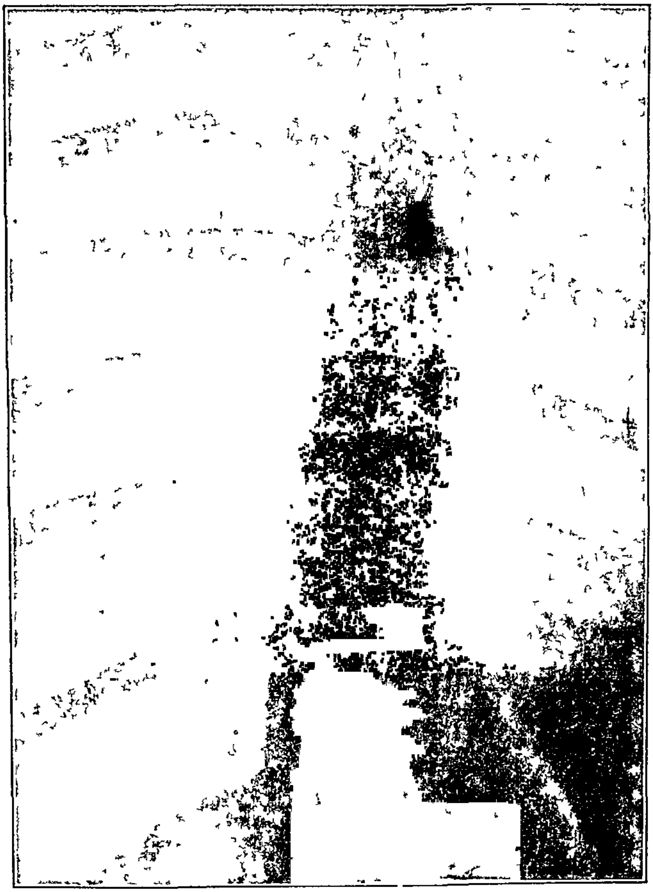
A CASE OF MEDICO-LEGAL INTEREST.

BY WILLIAM HENRY BATTLE, F.R.C.S. ENG.,
SURGEON TO ST. THOMAS'S HOSPITAL.

ON Saturday, the 18th of October, 1913, two people, a man and a woman, were found shot in a London hotel, and Dr. J. R. Ryan and Dr. T. M. Ness were summoned to see them. They telephoned me, and I saw the patients not long afterwards in consultation with them. When the patients were first seen, after the door had been opened with a pass key, they were lying in parallel beds, placed closely together, and the man occupied the one to the left of the woman. The beds had to be separated to permit the wounds to be examined. The man was the more seriously injured of the two, and when I saw him he was lying on his back, and showed symptoms of severe shock. By his side, parallel with his right hip, outside the bed, at about the length of the arm, was a small revolver, the butt end of which was turned towards him, whilst the muzzle pointed downwards. It was placed in such a position that if he had put it there himself he must have placed it with care, and with the hand supine. Dr. Ness assured me that this weapon had not been moved since he had entered the room. Alarm was first excited in the hotel by the sound of two shots in quick succession.

Examination of the male patient showed a round bullet wound, the edges of which were burnt by the close discharge of the weapon. There was no wound of exit. The wound, which had not bled very much, was situated on the left side of the middle line, about an inch and a half below the nipple and about an inch to the inner side, and had penetrated the chest through the intercostal space. There were loss of respiratory sounds and hyper-resonance on this side. His pulse was small and very rapid, but he had no dyspnœa. There had been no hæmoptysis. The wound was cleansed with an antiseptic and dressed. A hypodermic injection of morphine was given, and later in the day, when his shock had passed off to some extent, he was transferred to St. Thomas's Hospital.

The woman, who was very excitable, was not much injured; the bullet had entered over the left lower rib about the anterior axillary line, and came out again about an inch and a half posteriorly in the same plane. The wound of entrance was marked with the powder and was exactly like that in the man. She was also transferred to St.



From a skiagraph showing position and size of bullet in the spinal canal (Dr. A. D. Reid).

Thomas's Hospital, where she rapidly recovered. Nothing abnormal was detected on examination with the X rays. The weapon was a small Browning repeating pistol, firing a bullet the size of the one shown in the skiagram.

The man continued in a very low state after admission, and it was found that he was unable to move his lower limbs. He had retention of urine. There was complete anæsthesia below the waist and entire loss of reflexes. The bullet was seen with the X rays, but this examination was unsatisfactory. As the condition of the man prevented full exposure it could not be definitely localised. It was, however, lying to the right of the middle line in the spinal region. As there was still a very rapid pulse with some hæmorrhage from the wound, he was placed under an anæsthetic in the evening. The wound was opened up and the lung examined. There had been very little hæmorrhage into the pleura; the wound of the lung could be easily seen, but the lung was collapsed and the pleura full of air. The pericardium which was immediately to the right of the wound was uninjured. The edges of the wound in the intercostal space were pared and the opening closed with sutures. There was a gradual improvement in the condition of the chest and the general state of the patient, but none in that of the paraplegia. Dr. A. D. Reid then carefully examined the patient with the X rays, and gave it as his opinion that the bullet was lying in the spinal canal at the level of the seventh dorsal vertebra (see illustration). On the chance that its removal might be of benefit in the relief of pressure, laminectomy was performed on Nov. 2nd and the bullet was removed. It was lying between the dura mater and the vertebra to the right of the middle line. No irregularity of the bone could be felt or seen. The bullet was not in any way fixed, and was easily lifted out when the cord had been retracted to the left. It had not lost much metal, being but slightly flattened at the tip as if it had been deflected by bone or something of a hard nature. The cord was evidently much bruised. Pulsation was visible to the level at which the bullet was lying, but not below that. The patient stood the operation very well and the wound healed satisfactorily. He thought that sensation improved in both legs, but the paralysis did not get any better. Retention with overflow was only prevented by catheterism, and cystitis developed, from the effects of which he died on Nov. 21st at 9 P.M.

No post-mortem examination was permitted and a verdict of suicide was returned by the coroner. The radiograph, which is an excellent one, enabled Dr. Reid to say that the bullet was lying in the spinal canal, at the level of the seventh dorsal vertebra, and it was exactly as he stated. As there was no trace of bone injury or splashes of lead on the bones, did the bullet enter the spinal canal by the intervertebral foramen and turn up? To gain this point did it travel along the inner aspect of the ribs, or pass direct to the foramen which was penetrated?

Questions which present themselves for solution are, Did the man shoot the woman and himself, as he stated? If the man shot himself, how was it the bullet was lying so much to the right of the wound of entrance that it was removed from the right side of the spinal canal? Would any healthy man lying in bed naturally place a revolver in such a position as that in which this one was found? Could a man who had received such a severe mental and physical shock place the weapon so? Is it probable? The shortness of the interval between the two reports makes it unlikely that the weapon changed hands.

These are the questions which would naturally present themselves in any medico-legal examination of the facts, but such examination was considered unnecessary in view of accompanying circumstances and the man's confession.

Harley street, W.

NASOPHARYNGEAL AND CERVICAL GLANDULAR TUBERCULOSIS IN CHILDREN.

By A. DINGWALL FORDYCE, M.D. Edin.,
F.R.C.P. Edin.,
EXTRA PHYSICIAN, ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH,
AND
E. W. SCOTT CARMICHAEL, M.B. Edin.,
F.R.C.S. Edin.,
ASSISTANT SURGEON, ROYAL INFIRMARY, EDINBURGH.

Physicians and surgeons, more particularly those connected with a hospital for children, are confronted daily with cases of this nature. Our views on the subject are based on the experience gained by the treatment and observation of a large number of hospital cases, and a not inconsiderable number of private patients. We consider the subject from the following points of view: (1) Etiology and pathology; (2) clinical course; (3) prophylaxis; and (4) treatment.

Etiology.

In children under 1 year. During the early months of the first year of life tuberculosis is a comparatively rare disease, but in cases in which it occurs it is often in relation to the structures of the middle ear. In children under 6 months of age middle ear and mastoid tuberculosis is relatively common. It may be suspected from three clinical signs and symptoms: (1) a watery discharge from the middle ear; (2) a soft, boggy, painless swelling over the mastoid process; and (3) facial paralysis. Facial paralysis coming on in a child under 6 months of age, unaccompanied often by discharge from the external auditory meatus, or by perforation of the tympanic membrane, or by external evidence of mastoid disease, is almost a pathognomonic sign of extensive tuberculous disease of the Eustachian tube, middle ear, and mastoid process. This fact is very important. A soft swelling, usually painless, which is somewhat diffuse over the mastoid process and causes the pinna to bulge forward, is equally suggestive of tuberculosis. In such a case there is often no discharge from the external auditory meatus. We have never seen such signs present in a child of this age who was *solely* fed at the breast. We are bound therefore to correlate the occurrence of such early tuberculous infection with the practice of artificial feeding, and, more particularly, with feeding with cow's milk. There is a marked predilection for the infection to affect the middle ear and the temporal bone, and it seems to us that this is explained by aspiration up the Eustachian tubes during the act of sucking. It is certain that as the child gets past the age of sucking, mastoid and middle-ear infection become less common, and the disease attacks other regions of the nasopharynx. In these cases the tuberculous infection is often very acute and virulent. If, however, the disease remains limited to the mastoid process and does not spread either to the cervical glands or cranial cavity, the prognosis is a good one. We would therefore draw attention to the facts that tuberculosis affecting the nasopharynx in children under 1 year of age, and especially those under 6 months, has a strong predilection to spread up the Eustachian tube, and that it invariably occurs in children fed with cow's milk.

Large hospital experience of glandular tuberculosis in children over 1 year has proved to us that one gland or set of glands in the neck is more liable than any other to be the site of infection. This gland is situated in a definite anatomical triangle in the upper part of the neck. It lies immediately below the posterior belly of the digastric, and between the internal jugular and common facial veins. It is the central point of conveyance of a large number of lymphatics. These are, indirectly, the auricular, the facial, and the submaxillary, but above all it is the gland which receives directly the lymphatics from that part of the nasopharynx which includes the tonsil. It has also intimate connexions with two other sets of glands: (1) half a dozen round the spinal accessory nerve as it enters the sterno-mastoid muscle; and (2) the carotid set, passing down in relation to the carotid sheath. It is important to understand these anatomical facts in order to realise the course of tuberculous infection in this region of the body. Why should this gland (jugulo-digastric) be more liable to infection by the tubercle bacillus than any other in the body? We must realise that it is almost invariably a secondary infection. Where, then, is the primary focus? Some years ago one of us (E. W. S. C.) examined the pharyngeal tonsils in a series of cases of glandular tuberculosis. Casual sections were made of the tonsil on the side on which the glands were proved to be tuberculous after operation. In nearly 20 per cent. of cases the tonsil was found to be the site of tuberculous infection. It was only natural to suppose that a more careful examination by means of serial sections of such tonsils would show a still greater percentage of tonsillar infection, and such has proved to be the case from the recent work of Stiles and Mitchell. Tuberculous infection of the tonsil, therefore, is now known to be extremely common, and we must refer to its pathology in order to understand the course of events in the common form of the disease.

Pathology.

Primary infection: tonsillar tuberculosis.—Tuberculous infection of the tonsil does not cause ulceration of its surface: we have never seen a case of tuberculous ulceration even in tonsils which were the seat of advanced tuberculosis. In our experience tonsils which are the seat of extensive tuberculous infection are not hypertrophied tonsils, but are, on the contrary, often small, ragged, and atrophic. Tonsillar tuberculosis is chronic in type and leads to fibrosis and shrinkage of the tonsil. It rarely causes caseation to such a degree as to lead to breaking down of the tonsil. In the early stages it begins in the form of one or two giant cell systems round the bottom of the tonsillar crypts. These gradually extend into the substance of the tonsil until the whole or part of the gland has become invaded by the disease. It is probable that the tonsil is often tuberculous months or even years before the disease spreads beyond its substance. When the disease reaches the outer boundary of the tonsil it sets up a peritonsillitis, which is often somewhat acute in character. It is not perhaps going too far to say that many of the cases of acute tonsillitis so-called, which are ultimately found to be associated with tuberculosis of the corresponding glands, are really peritonsillar infections, and due to the spread of the disease beyond the tonsil. We have seen numerous instances where an attack of acute tonsillitis has led to the discovery of an advanced glandular tuberculosis.

Secondary infection: glandular tuberculosis.—Tuberculous infection in a gland begins as isolated foci which are often of different ages and stages of development. On examining such a gland removed at operation these multiple foci are seen distinctly, and consist of a caseating or calcareous centre with a surrounding capsule of fibrous stroma. When the tuberculous condition is progressive these foci continue to grow, and sooner or later one reaches the surface of the gland, involves its capsule, and sets up an inflammatory condition around the gland (periadenitis). This may follow one of two courses: (1) The periglandular tissue becomes congested and œdematous. This leads to extensive swelling which persists for some weeks and finally subsides. (2) This process does not resolve but passes on to the formation of an abscess outside the gland, which ultimately makes its way to the skin surface. In a large number of cases the periadenitis subsides, but another similar attack is liable to occur, and frequently recurring attacks end sooner or later in abscess formation. It is interesting to note that these recurrent attacks of periadenitis are not due to mixed or septic infection, and we would emphasise the resemblance in this respect between periadenitis and peritonsillitis already referred to. One of us (E. W. S. C.) has examined the pus and tissues from these cases of periadenitis on several occasions, and has failed to demonstrate the presence of any pyogenic organisms.

Clinical Course.

The following are examples of cases.

CASE 1.—A female aged 6 years. She was a healthy baby of healthy parents, and was brought up on the bottle and given large quantities of milk and cereals early. Purely pap feeding was continued through the second year, and no animal food was given other than milk or an occasional egg. Digestion and health were generally fairly good. When 2½ years old she suffered from acute tonsillitis. A throat-swab showed streptococci. The cervical glands on one side of the neck rapidly enlarged and became matted by periadenitis. In the course of about 10 days the throat condition had largely subsided, but in the neck a lump of the size of a small orange remained. In spite of general treatment glandular enlargement persisted. The tonsils were not markedly enlarged, but were ragged and unhealthy-looking. Operation on the tonsils or on the glands was refused. The child continued in fairly good though uncertain general health. An excessive carbohydrate diet was persisted in and the mass of glands gradually softened. When aged 6 years, along with pharyngeal catarrh, the enlargement rapidly increased and a large abscess was developed which threatened to rupture externally. On operation being performed extensive tonsillar tuberculosis, with a large abscess and numerous broken-down tuberculous glands in the neck, was found.

CASE 2.—A female aged 4 years. She was taken ill suddenly with influenza. She had a high, swinging temperature, sore throat, and greatly enlarged tonsils, with numerous white patches on the surface. A throat swab showed streptococci. On recovery from the acute attack the tonsils and adenoids were removed and found to be tuberculous. Six months later as a mass of glands remained on one side of the neck it was removed and found to be tuberculous, CASE 3.—A male aged 18 months. He was a healthy baby at birth. He was brought up on the bottle and fed largely on patent foods and medicated milk. He had constant digestive difficulties, and developed slight rickets, with distinct symptoms of the presence of adenoids and unhealthy-looking ragged tonsils. At the age of 14 months he developed acute tonsillitis with great enlargement and matting of glands on one side of the neck. Two months later excision of adenoids and tonsils showed tuberculous infection throughout.

Such are common and typical cases of apparent acute outset. But the occurrence of sore-throat and acute and marked glandular enlargement is no evidence of the period of onset of the tuberculous infection, and in most cases the tonsil has probably been the seat of a latent tuberculous infection for some considerable time previously. Generally speaking, the younger the child affected the more acute is the course of the disease. When the disease runs throughout a chronic course we take it that the course is nevertheless similar to that in an acute case. The difference here is that the conditions of peritonsillitis and periadenitis are slighter and may not be recognised clinically. The first evidence of the presence of disease is then the appearance of a single mobile gland in the side of the neck. This gland may lie latent for years, and, beyond a slight variation in size from time to time and an occasional slight attack of periadenitis, it does not attract much attention. A focus in its substance, however, may at any time become active and lead to the formation of an abscess.

Prophylaxis.

Tuberculous infection of the tonsils and cervical glands occurs in cases in which, apparently, every rational method of procedure has been adopted. Often, however, it is far otherwise. It is not our object at present to direct attention to the infecting agent—the tubercle bacillus. Suffice it to say that, however large or however small a proportion of cases it may be which are infected by the bacillus of bovine origin, it is always wise to give only *scalded milk* to a baby during the first two years of life. Prevention otherwise naturally consists in the maintenance of good general nutrition and of a healthy condition of oral and nasopharyngeal tissues. For the attainment of these ends two factors are of great importance—diet and oral hygiene.

The foundation of tuberculous disease of the cervical glands is over and over again laid in the manner of infant feeding. Unsatisfactory digestion, imperfect nutrition, eructation, vomiting, and consequent nasopharyngeal catarrh ensure a suitable nidus for infection. The advantage to a baby of receiving his mother's milk is too obvious to need more than remark. If he is not suckled he should receive during the first two years of life no cow's milk which has not been scalded. He should be fed on fixed quantities at definite intervals. This is the most important rule in infant feeding, and the one which is generally most necessary to emphasise. Within reason the actual composition of the food for a healthy baby is much less important. Cow's milk, condensed milk, patent foods—babies thrive well on all or any of these. Some are better than others, but most healthy babies would thrive on any if judiciously handled. But irregularity and uncertainty in time and amount of feeding are always dangerous, and usually have disastrous results. Irregularity of feeding times nearly always means feeding at too short intervals, and uncertainty of the requisite amount at each feed usually ends in overfeeding. In both cases regurgitation and often vomiting tend to occur. Catarrh of the pharynx is set up, and in association with disordered digestion and its effects on nutrition, a favourable locus is provided for infection. For the same reason cereals or patent foods containing unaltered starch should be avoided as a rule during the first six months of life.

The commencement of primary dentition—the latter half of the first year—is a period of great importance from the dietetic point of view. Starch now is a valuable element in the diet, the chewing and gnawing of hard food has to be encouraged, and simple animal food, such as gravy, clear soup, and lightly boiled egg, has to be gradually included in the diet sheet.

We would emphasise the importance of accustoming the baby to gnaw a tough crust or a thick, strong bone. Oral hygiene largely consists in facilitating the cleansing of the mouth by saliva, and by no means can this be better attained than by such gnawing and chewing. During the second year considerable variety of food is good, hard food is useful, and meat becomes an important element of the diet.

Here we would lay stress on a prevalent misconception regarding the value of meat in the diet of young children. Constantly we see otherwise healthy children suffering from indigestion due to overfeeding with bread, porridge, potatoes, biscuits, cakes, sweets. Comparatively rarely do we see indigestion due to excessive meat-eating. Most certainly a large amount of meat in the diet of a healthy young child is likely to cause digestive trouble. But the point is that an adequate supply of flesh meat and fish in the daily diet is not only beneficial, but is, as a rule, necessary for the maintenance of health. During the first half of the second year the child should get this animal food in the form of egg, bacon, or fish. Thereafter he should be given daily at dinner a little chicken, rabbit, or butcher's meat. We consider that deficiency of animal food—in the shape of meat, fish, and eggs—in the diet, along with the common coexistent carbohydrate dyspepsia, is a widespread and important underlying factor in the development of various infections, and is more particularly one of the primary causes of the vast amount of cervical glandular tuberculosis.

Treatment.

As has been indicated, the onset of obvious enlargement of the glands is often sudden. The child is seized with a general illness of the nature of a "cold" or influenza, there is acute pharyngeal catarrh and often marked tonsillitis, and coincidently there is glandular swelling in the neck. With ordinary mild antiseptic local treatment the acute condition in the throat subsides in the course of a few days, but the glandular enlargement remains. Von Pirquet's reaction is strongly positive. There is a mass on one side of the neck of the size of a small orange and adherent to the surrounding tissues. The mass is firm and at first tender on manipulation. On the other side of the neck there are usually one or two small firm discrete glands to be made out on careful palpation. Under no circumstances should operative interference be carried out when peritonsillitis or periadenitis is present. Surgical interference is only indicated after or between such attacks.

The first and obvious procedure is to seek to remove the acute periadenitis by means of boric poultices or ichthyol (20 per cent.) applications locally, and to paint the throat with a mild antiseptic (boroglyceride). As the condition improves the tenderness disappears, the glands appear firmer and more readily movable, and the mass shrinks to some extent. During this period no other routine medical treatment should be employed and tuberculin should certainly be avoided. The general health of the child, however, requires careful attention. Often it is quite good, but sometimes there are want of appetite, lassitude, and various signs of disturbed metabolism. Usually, however, there is no swinging temperature. Four to six weeks after the onset of the condition the tonsils and adenoid tissue should be removed. This should be done in every case, whether there is apparent enlargement or not.

Following on this operation the child should be ordered a change of air for about two months. If it is summer-time and the weather warm the sea coast is suitable, but as a rule an inland part of the country at some height is better. During this time the child is in the open air as much as possible, is given plenty of simple food at regular intervals, and in particular receives a sufficiency of animal food. As a matter of routine the administration of tuberculin is inadvisable. If the child can be given all the stimulating and invigorating advantages which accrue from a suitable change of air and scene and a well-regulated diet, tuberculin gives nothing more. If, on the other hand, the best environment in all respects cannot be obtained, tuberculin is of value. Tuberculin T.R. is given in small doses every tenth day. For a child of 2 years one begins with a dose of 1/8000th of a milligramme and increases to 1/6000th; for a child of more than 5 years one begins with a dose of 1/6000th and increases to 1/4000th. The attempt is to avoid any general reaction. At the end of two months—i.e., between three or four months after the onset of the acute condition—the question whether or no operation is advisable should be decided. In all cases, however, where before this time there has been evidence of active disease as shown by recurring attacks of periadenitis, operation should be advised. This is particularly the case when the tonsils have been found to be extensively diseased.

The younger the patient the more active the disease as a rule, and the greater the need for surgical interference. If there is a definite history of family predisposition to tubercle infection, and, more particularly, if a member of the household suffers from tuberculosis, and if the glands have not distinctly shrunk, they should be removed at once, irrespective of the general condition of the child. The probability in such cases is that sooner or later they will break down. If there is no such history, however, if the general condition of the patient is not quite satisfactory, and if the glands show no distinct signs of shrinking, or if the disease is spreading to the spinal accessory or carotid set of glands, or if there are signs of abscess formation—again operation should be advised at once. If the general condition is good and the glands are distinctly smaller, operation is not advisable, and there is good ground for the hope that, under a careful regimen, the condition will undergo a natural cure. If the general condition is not quite satisfactory, but the glands are rather smaller and firmer, or, again, if the general condition is good but the glands are not distinctly smaller, a course of tuberculin should be employed for a further period of at least two months. If at the end of six months from the acute onset, in the one case the general condition is still unsatisfactory, or in the other the glands are still markedly enlarged, they should be removed. In cases, chronic from the commencement, where a gland persists for more than a year and tends to get larger, its removal is desirable.

MODERN TREATMENT OF LACRYMAL OBSTRUCTION.

BY D. LEIGHTON DAVIES, M.D., M.S. LOND., F.R.C.S. ENG.,

ASSISTANT LECTURER AND DEMONSTRATOR OF ANATOMY, UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE; ASSISTANT OPHTHALMIC SURGEON TO THE CARDIFF INFIRMARY.

THE recent discussion at the annual meeting of the British Medical Association on the treatment of lacrymal stricture appears to have been of little practical value, for it has left us in much the same state as we were in before. My object in writing this paper is to appeal to ophthalmic surgeons for a wider trial of rational lines of treatment in cases of lacrymal duct obstruction.

For many years ophthalmic surgeons have been satisfied with the old-established method of probing; but of late years there has been a growing tendency to resort to other methods. The large number of lacrymal sacs that are now excised annually bears eloquent testimony to the unsatisfactory results from probing. Undoubtedly probing does at times meet with brilliant success, but such cases cannot be frequent, else why this wholesale excision of sacs? The reasons for the failure of the various probing methods are numerous. Amongst them is the tendency for the stricture to close, necessitating repassing of probes at intervals for years, or at any rate until the patient gets tired of the treatment. Let us think for a moment what is likely to happen in the passage of a full-sized probe. A certain amount of force, more or less, is used, and this must in all probability actually denude the lacrymal canal of its mucous membrane at the point of greatest pressure. We cannot even be certain that the probe does not pass through a tear in the mucous membrane and for the rest of its course pass down between the mucous membrane and the bony wall of the canal.

Compare the conditions to be found in a case of urethral stricture. There we know that fibrous tissue replaces the ordinary mucous membrane, and after the relief of a tight stricture by the passage of bougies it is recognised by surgeons that the cure is not permanent, but the patients are usually instructed to present themselves at regular intervals for the passage of bougies. Neglect of this advice sooner or later results in a recontraction of the stricture. How can we expect the lacrymal canal to differ in its course and progress when treated on the same lines?

The use of styles following probing has had a good many advocates. They do not always relieve, in many cases they are a source of discomfort, and in not a few cases have patients presented themselves at the hospital with marked cellulitis of the tissues round the orbit due to a forgotten style, which in some cases had been there for years and was extracted with difficulty.

I now pass on to the question of the extirpation of the sac, the various methods for which are numerous and need not be discussed. In favour of this method, which, indeed, is a great advance on probing, is the fact that it shortens treatment; it is an effectual preventive of those suppurative affections of the sac which frequently follows stricture. It is, however, a mutilation, and from that point of view an unsurgical procedure in the highest sense of the term. But in saying this I do not deny that many cases are best treated by extirpation of the sac; among such one would mention tuberculous disease of the sac or those in which a bad fistula was present in patients advancing in age. Against it also has been urged the statement that infectious conditions of the conjunctiva are more frequent, more difficult to cure, and more liable to relapses after removal of the sac. I do not know on what evidence this statement has been made, but certainly in my own comparatively small number of cases in which I have removed the sac I have never had to treat infectious diseases of the conjunctiva of the corresponding eye. And here it will be appropriate to allude to a case of congenital bilateral absence of the puncta in a youth under my care. So far as can be ascertained he has never suffered from any inflammatory affections of his conjunctiva. Undoubtedly, therefore, there are many cases in which extirpation of the sac is the wisest and best course to pursue, though I believe that it is a procedure which should be only undertaken after a very careful and comprehensive survey of each individual case, and I believe that as our experience ripens we shall find that fewer and fewer sacs will be excised and that more rational and surgical lines of procedure will be followed.

The ideal treatment is, of course, to restore as far as possible the natural drainage of the sac. The best means by which this can be done at the present time appears to be the method elaborated by Toti, or, to give it its rather cumbrous name, dacryocystorhinostomy. This is a genuine attempt to meet the surgical requirements, though probably the future will see further improvements on these lines. There is no need that I should here go into a minute description of the operation. It will suffice to say that it consists of two steps: (1) exposure of the lacrymal sac in its fossa and removal of its inner wall; and (2) the removal of the inner wall (in part) of the lacrymal fossa and the mucous membrane of the nose lying against it. By this means the tears drain directly from the sac into the anterior part of the middle meatus of the nose or the vestibule.

Whilst most ophthalmic surgeons seem to know of the operation, yet so far as I am aware Mr. Charles Higgens is the only one in this country who has reported on this particular operation, and he recorded three cases before the Ophthalmological Section of the British Medical Association at the annual meeting this year.

For the past two and a half years I have been doing Toti's operation on selected cases, and have now actually done 10. Of these 10 cases, 7 have been and are, so far as I can trace them, completely cured of their epiphora. Two patients were only partially relieved—that is to say, they still complained of watering of the eye when I last saw them; though it was possible, but with difficulty, to syringe fluid through into the nose. However, the purulent discharge which they had had previous to the operation has not returned. One case was a failure owing, I think, to faulty technique on my part. The lacrymal fossa was deep and not easy to get at, and I believe the opening into the nose was insufficient. This, of course, is not a large series of cases, and one is not justified in claiming too much for the operation, though the results are sufficiently encouraging to induce me to give the method a much more extended trial.

Let us now consider what the critics of this operation urge against it.

1. Its difficulty. Most of the surgeons who have mentioned this operation, but who, I believe, have not done it, urge against it its great and inherent difficulty. For example, in opening the discussion on the subject of treatment of chronic dacryocystitis at the British Medical Association meeting already referred to, Mr. Harrison Butler made this remark: "I think that Toti's method would be always exceedingly difficult and tedious, and in most cases quite impossible," &c. Others have spoken in still stronger terms about it. Without doubt the operation requires that the surgeon should have an intimate knowledge of the anatomy of the lacrymal sac, together with its fossa and its relation to surrounding parts, and surely every ophthalmic surgeon should be expected to know the anatomy of the orbit, its surroundings, and contents to the minutest details, seeing that he is dealing with so restricted an area. Excision of the lacrymal sac itself needs a clear knowledge of the parts involved and is not a simple operation. Toti's operation is in reality very little more difficult. As my experience has increased so the time for completing the operation has lessened, and I find that half an hour amply suffices in uncomplicated cases.

2. A second objection urged against the operation is the danger of infection of the conjunctiva from the nose. My own series of cases does not bear this objection out, for not a single case has ever had the slightest trouble from that cause. Why should it be more likely to occur after this operation than in a stricture which has been dilated? In the latter case the mucous membrane has probably shed most of its epithelium and is itself in a more or less septic state; an easy channel whereby organisms may travel up from the nose to the conjunctival surfaces. It seems to me, therefore, that this objection would apply with greater force to methods in which probing is the main procedure.

3. Again, it has been urged that there would probably be a good deal of discomfort during the process of blowing the nose from the fact that there is such a free communication between the lacrymal sac and nasal cavity. This is an objection which I fully expected to find, but though I have questioned patients about it they have none of them experienced the slightest inconvenience. In connexion with this I might mention the following case in my series.

A patient, a woman aged 40, had had lacrymal obstruction on both sides for over a year. She had been treated on one side by another surgeon by probing with so little success that after many weeks of discomfort she ceased the treatment. Becoming neglectful, she developed an abscess of that sac, which burst and left a fistula on the face. She then came under my care. I excised the sac on the side where the fistula was situated, and later did a Toti's operation on the other side. To-day, some two years after the operation, the side on which the anastomosis was done is the more comfortable of the two. This, I think, will speak for itself.

These, then, are the answers I would make to the various objections to Toti's operation. Hitherto the subject of the treatment of lacrymal stricture has not received as careful a consideration as it demands. Often the subject is almost neglected. Lately, indeed, some awakening of interest has shown itself since the introduction of the operation of extirpation of the sac. But this is not to be the end of all progress, and I would appeal to those ophthalmic surgeons in this country who are interested in the subject of lacrymal stricture to give Toti's operation or its congeners a trial with the hope of elaborating still better methods. Let us face the facts. Why should ophthalmic surgeons hesitate to perform an operation which involves the nasal passages? The regions in contiguity to the orbit belong as much to the ophthalmic surgeon as does the cranial cavity to the aural surgeon and, as I have already said, every ophthalmic surgeon should be thoroughly *au fait* with the anatomy of the whole of the orbital and peri-orbital areas and be prepared to deal with the various conditions, orbital or lacrymal, which involve these. I am sure, and in this most surgeons will agree with me, too many sacs are excised. And yet, apart from treatment by probes, a method which is slowly but surely coming into disrepute as a routine measure, and justly so I think, there is no other line of treatment to adopt. It is for this reason I have ventured to place on record the few cases of Toti's operation I have done, with the hope that others will be encouraged to adopt similar methods, and so assist in bringing about a line of treatment more calculated permanently to benefit our patients.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF DERMATOLOGY.

Exhibition of Cases.

A MEETING of this section was held on Dec. 18th, 1913, Dr. J. J. PRINGLE, the President, being in the chair.

The PRESIDENT exhibited a man, aged 30, with typical Fordyce's Disease of the Lips of about 15 years' duration. The subjective symptoms were greatly disproportionate to the visible changes as is frequently observed. The case was brought forward chiefly to obtain the opinion and experience of members as to treatment. His personal results from the use of X rays had been disappointing. He had heard of the successful use of radium in one such case, probably employed "naked" in small and frequently repeated doses, and he proposed to apply this method of treatment in the case shown.—Dr. W. K. SIBLEY recommended salicylate of soda cataphoresis; Dr. G. PERNET, electrolysis; Mr. T. P. BEDDOES, arsenical paste; and Dr. A. WHITFIELD advocated the surgical removal of skin and subsequent grafting if no good results were obtained from full pastille doses of X rays.

Dr. DUDLEY CORBETT brought forward a man who had contracted syphilis and who now presented marked Macrocheilia; the Wassermann reaction was positive; the patient was a heavy smoker and had a very septic mouth.—Dr. J. H. SEQUEIRA had seen a similar case greatly improved by salvarsan.—Dr. E. G. GRAHAM LITTLE suggested extracting the teeth.—Dr. WHITFIELD recommended the use of salvarsan combined with mercury and the removal of the teeth.—Dr. A. M. H. GRAY and the PRESIDENT added their testimony to the efficacy of salvarsan in such cases.

Mr. BEDDOES exhibited a recent malignant growth on the finger of a medical man who had suffered from X ray dermatitis for at least nine years.—Dr. SEQUEIRA recalled a similar case observed by Darier which developed eleven years and seven months after exposures to X rays.—Dr. WHITFIELD had observed the appearance of an X ray ulcer 12 years after X rays were employed to locate a needle in the foot.—Dr. H. G. ADAMSON pointed out that this case illustrated the fact that epithelioma might be consecutive to large as well as to repeated small doses of X rays. The three previous speakers all strongly advised free excision of the growth.—Dr. GRAHAM LITTLE referred to a case observed by Darier, arising in circumstances identical with that reported by Dr. Whitfield, and Dr. G. N. MEACHEN mentioned two cases of severe dermatitis occurring five and seven years respectively after the X raying of scrofulous glands and ringworm.—Dr. W. KENNETH WILLS (Bristol) said that he had found carbon-dioxide snow useful in the removal of warty growths resulting from X rays.

Dr. S. E. DORE showed a severe Frambœsioid Syphilide of the hairy parts of the face in a man. The Wassermann reaction was negative but the patient had been taking Donovan's solution.—The PRESIDENT suggested that the appearance might in part be due to the iodine which he had taken, and agreed with the exhibitor as to the marked benefit afforded by salvarsan in such cases.

Dr. DORE also showed a boy, aged 4½ years, with Congenital Hyperkeratosis of the Palms and Soles which was noticed at birth. Similar keratoses were present over the elbows and knuckles and dorsal aspects of the ankles. He discussed the relationship to ichthyosis, and thought that in view of the difficulty of classifying these cases it was better to retain the name of congenital hyperkeratosis.—Dr. J. M. H. MACLEOD thought the condition had best be classified as a form of nævus, and said that in true ichthyosis the palms and soles were rarely affected.—Dr. F. PARKES WEBER considered that keratoses of the extremities constituted a class by themselves.—Dr. WHITFIELD and the PRESIDENT, while agreeing that such cases as that exhibited were not examples of true ichthyosis, differed from Dr. MacLeod, and were of opinion that in true ichthyosis the palms and soles were almost invariably involved to some extent, although not in the manner exhibited in the patient.

Dr. DORE also showed a case of Congenital Alopecia in a boy, aged 2, which had been complete at birth, but tufts of hair had since grown on the vertex and in the occipital region and elsewhere. The Wassermann reaction was negative.—Dr. SEQUEIRA'S experience was that the Wassermann reaction was negative in all such cases.

Dr. DORE also showed a well-marked example of Bromide Eruption of Granulomatous Type in an infant of 8 months, the origin of which could not be determined, although a teething-powder administered was open to suspicion.

Dr. W. T. FREEMAN exhibited a typical Dermatitis Artefacta, confined to the left arm, in a girl aged 22, which had been provoked since a burn three years ago; many of the resulting scars had recently become cheloidal.

Dr. PERNET also brought forward a case of Dermatitis Artefacta of about six months' duration on the right arm of a woman. The lesions were obviously produced by a powerful escharotic the nature of which he had been unable to determine.—Dr. SIBLEY, Dr. SEQUEIRA, and Dr. J. H. STOWERS discussed the cases.

Dr. MACLEOD exhibited a boy who presented the lesions of Lichen Spinulosus as well as those of Lichen Planus. The lichen spinulosus had been present for about four years, but the lichen planus had developed on the flexor aspects of the arms and legs only within the last few weeks. He considered that two different conditions were present in the same patient, and that the case was not an example of the lichen planopilaris which had been described by the President.—The PRESIDENT concurred in Dr. MacLeod's view, and added that the disease with which his name had been associated occurred in adults, and that the spiny and plane lesions which developed successively were probably clinical expressions of one pathological condition.—Dr. ADAMSON said that lichen spinulosus in the adult was in his experience always the precursor of lichen planus.—Dr. WHITFIELD was of opinion that spinulosus papules might occur any time before the onset of a lichen planus, and did not follow the same course.

Dr. SIBLEY showed a case of Extensive Erythematous Lupus of the Scalp and Face treated with carbon dioxide snow dissolved in acetone.—The treatment was discussed and criticised by the PRESIDENT, Dr. SEQUEIRA, Dr. ADAMSON, Dr. DORE, Dr. A. DOUGLAS HEATH, Dr.

MACLEOD, and Dr. GRAY, all of whom agreed that the essential condition for success was the production of a superficial atrophy after an appropriate amount of cutaneous reaction.—In reply, Dr. SIBLEY stated that the pain produced was not unduly severe, and that the method was applicable both to the "fixed" and more diffuse vascular types of the disease.

Dr. SIBLEY also showed a case of Stomatitis Neurotica Chronica of 10 months' duration in a nervous woman, aged 38; the lesions were situated on the buccal mucosa and on the dorsum of the tongue, and were always aggravated by worry. The condition had been differentiated by several continental observers, and he had published three cases in 1899, one of them being of 25 years' duration.—Dr. ADAMSON regarded the case as annular lichen planus.—Dr. PARKES WEBER had seen one similar case successfully treated with a weak solution of chromic acid.—Dr. J. GALLOWAY had observed several identical cases which he regarded as the result of oral sepsis.—The PRESIDENT was quite familiar with the condition, which he had long considered to be one of recurrent herpes. They were certainly frequently associated with neurotic dyspepsia.—In reply, Dr. SIBLEY said that none of his cases had ever developed lichen planus, and in one patient all the teeth had been removed without improvement.

Dr. GRAY exhibited an example of Parapsoriasis-en-plaques, of three years' duration, in a middle-aged man, the patches being situated on the thighs, legs, arms, and back. Great improvement, especially as regards diminution of the itching, had resulted from the use of the Kromayer lamp.

Dr. SEQUEIRA exhibited a case of extremely severe Lichen Scrofulosus in a boy, the whole surface of whose trunk was covered with a papular eruption closely resembling lichen planus, for which the disease was at first mistaken. Microscopical examination, however, revealed distinct tubercular architecture.—Dr. R. A. BOLAM had seen an identical eruption, but localised on the face.—Dr. ADAMSON and Dr. MACLEOD concurred in the diagnosis of a tuberculide, but Dr. WHITFIELD regarded it as a lichen planus.—The PRESIDENT would have diagnosed the case as lichen planus, but was bound to accept the microscopical findings as conclusive.

Dr. SEQUEIRA also showed a case of Multiple Neuromata in a woman, aged 56, the whole of whose body presented innumerable pigmentary patches and small tumours, which had been present since childhood. The diagnosis was in doubt until microscopical examination revealed the true neuromatous nature of these growths which brought the case into very close affinity with Recklinghausen's disease.

Dr. GRAHAM LITTLE showed a lad with a tumour of recent growth, about the size of a tangerine orange, on one knee, which he thought was probably a fibro-sarcoma, but some of the members present regarded it as a lymphatic nævus.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Discussion on the Sale of Milk.

A MEETING of this society was held on Dec. 12th, 1913, Dr. A. K. CHALMERS, the President, being in the chair.

A discussion on the Sale of Milk was opened by Dr. H. JOSEPH CATES, medical officer of health of St. Helens. He referred to the unsatisfactory state of the law with respect to the sale of milk and to the difficulties connected with the prosecution of those who supplied milk which was of an unsatisfactory character. The Sale of Milk Regulations issued by the Board of Agriculture in 1901 provided that a sample of milk which contained less than 3 per cent. of fat should be presumed until the contrary was proved not to be genuine. Where the contents of a sample were found to be below this percentage, and where proceedings were taken against the vendor, various defences were set up. In a case at Lancaster where a milk-seller was prosecuted for selling milk which was admittedly 23 per cent. deficient in fat according to the Board's standard, a successful defence was raised by the cowkeeper from whom the milk was purchased testifying that the milk when sold was in the same condition as when it came from the cows, and witnesses were called to show that normal healthy cows could give milk containing as little as 1·7 per cent. of fat. Factors which were said to cause a variation in the amount of fat in milk included seasonal variation, the period of lactation, the interval between the times of milking, the method of milking, the quality and amount of food, and the particular breed of cattle. The effect of establishing a sort of minimum standard had been to bring about what was known as the "toning" of milk, which consisted of the addition to a naturally rich milk of water or more commonly of skimmed milk in sufficient quantities to bring the resultant mixture into line with that standard. With almost mathematical exactness samples of milk would show on analysis 3 per cent. of fat, almost proving that careful manipulation was taking place. In a certain town when it was decided to take proceedings only when the percentage of fat fell to below 2·7 a progressive deterioration immediately followed in the quality of the samples taken. Although he admitted that there was much to be said against the fixing of a minimum standard as regarded milk, Dr. Cates was of opinion that it would be of some value, and he considered that cows that habitually gave milk of a quality considerably below the limit which was fixed should not be used as milkers.

Mr. WILFRED BUCKLEY, who had established a dairy farm in Surrey on lines similar to those which supplied certified milk in America, insisted that milk should only be sold as "certified" if its production had been approved by a body that had no direct interest in the milk trade and he urged that this could only be done by the establishment of a Government certification.

Sir SHIRLEY F. MURPHY spoke of the extreme difficulty of determining what was good milk and thought that it might be better not to fix any standard. He agreed that the milk of a cow producing poor milk should not be sold.

Dr. B. BURNETT HAM said that in Australia there was a Departmental Committee representing various interests capable of dealing with all aspects of the milk trade. In Victoria there was a standard of 3·5 per cent. of milk fat, probably the highest in the world. After some years' experience it had been found to inflict no hardship on producers, and it had been found possible to maintain the standard.

Dr. A. W. J. MCFADDEN was afraid that with the high standard in Australia there must be a great deal of toning down of milk. He referred to the provisions in the latest Milk Bill dealing with the purity of milk, and especially as regards the addition of colouring matter and of skimmed milk and of water.

Dr. A. B. MACMASTER advocated the grading of milk as practised in America.

Mr. HERBERT JONES hoped that grading would not be introduced into this country as it would put a premium upon the production of milk under most unsatisfactory conditions, for farmers would continue to supply dirty milk on the plea that it could be sterilised and thus rendered harmless.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Specimens.—Relation of Blackwater Fever to Malaria.

A MEETING of this society was held on Dec. 11th, 1913, Dr. J. LLOYD ROBERTS being in the chair.

The following specimens were shown and described:—

Dr. H. LEITH MURRAY: Three cases (two of which were under the care of the late Dr. A. Wallace) of Adenomyoma of the Posterior Vaginal Wall immediately below, but distinct from, the cervix. In two of these the growth, histologically simple and identical with a uterine adenomyoma, burrowed through the recto-vaginal septum and infiltrated the wall of the rectum. Dr. Murray discussed the etiology.

Dr. N. RAW: Carcinoma of Stomach involving Œsophagus.

Mr. T. O. LITLER JONE[illegible] with Papilloma of the Ureter; [illegible] Jaw.

Mr. LITLER JONES and [illegible] uman Hairball.

Mr. G. P. NEWBOLT and Dr. W. MURRAY CAIRNS: Human Hairball weighing 4½ lb., which had been successfully removed by Mr. Newbolt from the stomach of a girl aged 16.

Mr. NEWBOLT: 1. Human Hairball weighing 9 oz., which he had successfully removed in the year 1908. In this case a bismuth X ray photograph clearly showed the outline of the hairball. 2. Round-celled Sarcoma of the Bladder Wall. 3. Carcinoma of the Kidney.

Mr. R. C. DUN: (1) Lymphadenoma; and (2) Vermiform Appendix containing Threadworms.

Professor E. E. GLYNN: (1) Two Human Hairballs; and (2) Hairballs from Animals.

Dr. W. B. WARRINGTON: Tumour in the Right Posterior Fossa of the Cerebellum. It was the size of a small walnut, growing between the fifth and seventh nerves. During life the only focal symptom was right corneal areflexia. The posterior fossa was explored on the right side, but owing to the interior and anterior site of the tumour its presence was not detected at the operation. Histologically the tumour was composed of innocent fibrous tissue.

Professor J. W. W. STEPHENS and Mr. F. A. G. JEANS: Chinese Lady's Foot. Surgically it was in a condition of pes cavus, whilst pathologically the deformity was mainly produced by a change in the os calcis, which was L shaped, the patient walking on the insertion of the tendo Achillis.

Professor STEPHENS: (1) Bilharzia of Bladder and Intestine; (2) Guinea-worm; (3) colour photographs from Lip of Tsetse Fly; (4) Redshank trapped by Cockle; (5) Fossil Tsetse Fly; and (6) Bot Parasite on Tapeworm.

Dr. W. BLAIR BELL: Sarcoma of the Ovary.

The specimens were discussed by Mr. F. T. PAUL, Mr. C. THURSTAN HOLLAND, Mr. NEWBOLT, and Mr. LITLER JONES.

Professor STEPHENS read a paper on the Relation of Blackwater Fever to Malaria.—Dr. W. T. PROUT discussed the paper, and said that he supported Professor Stephens in his view as to the relationship between malaria and blackwater fever. The more he had seen of this disease in the tropics, and his experience was very considerable, the more he was impressed from a clinical point of view with its relationship to malaria. He thought some of the figures cited by Professor Stephens very convincing, and he considered that additional confirmatory evidence might be cited in the results of the prophylactic use of quinine. Where this had been systematically done it had been found that blackwater fever had diminished as well as malaria.—Dr. LLOYD ROBERTS, Mr J. BRADLEY HUGHES, Dr. C. O. STALLYBRASS, and Dr. R. E. HARCOURT also spoke, and Professor STEPHENS replied.

MIDLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Extra-uterine Gestation occurring Twice in the Same Patient.—Tubal Mole.—Suppurating Hydropyonephrosis complicating Pregnancy.

A MEETING of this society was held at the Royal Infirmary, Derby, on Dec 2nd, 1913, Professor WALTER C. SWAYNE, the President, being in the chair.

Mr. H. T. HICKS showed two specimens of Chorion-epithelioma occurring after Pregnancy at Full Term. The first specimen was obtained at the necropsy on a patient who had given birth to a full-term living child about three months before death. A small nodular growth was present in the uterine muscle close to the left cornu, and metastases were found in the lungs, kidneys, liver, and other viscera. An important point in connexion with the case was the absence of uterine hæmorrhage. Apart from a slight loss of blood about 16 days after delivery, uterine symptoms were absent. The patient was admitted as an acute liver condition. The hepatic area was explored and small secondary growths in the liver were found at the time of operation. Microscopical sections revealed the nature of the neoplasm. The second specimen consisted of a uterus enlarged to about the size of a two months' gestation and containing a diffuse dark-coloured necrotic growth, which had the typical characteristics of chorion-epithelioma. The organ was removed from a patient who had suffered from attacks of bleeding for a month after delivery at full term. A small embolic growth was present in the anterior wall of the vagina; this was also removed. The patient was operated upon six weeks after delivery, and nine months later was apparently in good health.—Mr. H. BECKWITH WHITEHOUSE described a case of Chorion-epithelioma which he had seen under the care of Dr. Thomas Wilson, and which only revealed its true nature when operation was required owing to severe intraperitoneal hæmorrhage. At the laparotomy the bleeding point was found in the left mesosalpinx, and was due to erosion of one of the veins in a pampiniform plexus by an embolic deposit. He was interested in Mr. Hicks's first case, particularly since he also had met with one example of chorion-epithelioma which had caused no uterine hæmorrhage and which was only discovered at the necropsy.—Mr. CHRISTOPHER MARTIN asked if any hydatidiform degeneration of the placenta was present in either of Mr. Hicks's cases. He would like to know in what proportion of cases hydatidiform mole preceded chorion-epithelioma.—The PRESIDENT thanked Mr. Hicks for bringing these two interesting cases forward. He was particularly interested in the same because he had had two very similar cases. In one, before operation, definite hæmoptysis was present which had been attributed to pulmonary metastasis. After operation the symptom disappeared, and the patient made a good recovery and remained well after several years. Leith Murray had shown that in some cases there is a definite tendency to retrogression of these growths.—Mr. HICKS, in reply, thought that Mr. Martin had raised a most important point as regarded the incidence of chorion-epithelioma to vesicular mole. The views of Teacher and Marchand were that the malignant growth as a rule follows the latter. In his own experience this had not been the case, since in a series of four examples three had succeeded full-term gestation.

Mr. HICKS next exhibited a specimen of a Complete Cast of the Female Bladder which had been passed per urethram. The patient had suffered from retention of urine, the result of pressure from a retroverted and incarcerated gravid uterus. The latter had to be emptied, and about a week later a small portion of the cast appeared at the urethral orifice. The whole cast was delivered by traction from below. The patient ultimately made a complete recovery.—Dr. C. E. PURSLOW related the details of a case where a complete cast of the bladder was passed by a woman who had had for a fortnight retention with incontinence due to a retroverted gravid uterus. The patient died from ascending infection of the kidneys.—The PRESIDENT also recorded details of a fatal case of exfoliation of the vesical mucosa secondary to retroversion of the gravid uterus.

Mr. HICKS also showed (1) a specimen of a large Tubo-ovarian Cyst of the left uterine appendage, a similar and smaller cyst being present in the opposite adnexa, and (2) a small Dermoid of the Left Ovary containing three teeth. The interest in the latter specimen lay in the fact that the patient was X rayed for diagnostic purposes, and the photograph showed three distinct shadows lying near the left sacro-iliac synchondrosis. The abdomen was explored for supposed ureteric calculi, when the small tumour containing the teeth was discovered, the latter accounting for the shadows.

Mr. MARTIN showed a Uterus and Both Appendages removed on account of Bilateral Tubal Gestation and small Multiple Uterine Fibroids.

Dr. PURSLOW exhibited a specimen of Unruptured Interstitial Ectopic Gestation removed from a patient aged 32, who had been married five years and had not previously been pregnant. Menstruation had been regular up to 10 weeks before operation. She then had amenorrhœa for six weeks, and subsequently on three occasions noticed a brown discharge. It was thought that there had been an abortion, and she was sent by her medical attendant to Dr. Purslow with a view to having curetting performed. On examination, the uterus was found to be slightly enlarged and a small swelling was noted attached to its right cornu. Tubal gestation was diagnosed. On opening the abdomen the swelling was found to occupy the right uterine cornu, the corresponding round ligament being attached rather to the inner side of the centre of the swelling. The tube was perfectly normal. The tumour was removed by excising a wedge-shaped portion from the wall of the uterus, the patient making a good recovery. No blood was present in the peritoneal cavity.

Mr. WHITEHOUSE read a short communication upon a case of Extra-uterine Gestation occurring Twice in the Same Patient, together with a Note on the Treatment of Tubal Mole. The author observed that the case raised an important point as to whether an operator is justified in removing the uterine appendage in cases of tubal mole or incomplete tubal abortion. Personally, he did not believe that it was good surgery to sacrifice the ovary and tube in these instances, since dissection of a number of specimens under normal saline had shown that the mole is only attached by a narrow base, and that no great difficulty need be anticipated in controlling the bleeding point. He suggested that access to the mole be attained by a longitudinal incision through the wall of the tube. After enucleation and control of the bleeding point the wall might be closed by a continuous suture of fine silk. With regard to the objection of total or partial occlusion of the tube, he did not think that the risk of such occlusion was as great in cases of tubal mole as in inflammatory conditions which are from time to time subjected to operation by salpingostomy and partial salpingectomy.—The PRESIDENT observed that with regard to Mr. Whitehouse's suggestion of conservative surgery for tubal mole the same idea had occurred to him, but he had deferred the experiment because he did [illegible] the tubal lumen.—Mr. MARTIN [illegible] number of cases of tubal mole [illegible] it could safely be delayed. As to operative treatment, he preferred the more radical method of salpingo-oöphorectomy, since he thought it was difficult to know what was the cause of ectopic pregnancy. Personally, he considered that the fault lay in the muscle rather than the mucosa of the tube. This being so, salpingotomy would favour the recurrence of the condition.—Mr. WHITEHOUSE in reply stated that he did not consider the risk of obliterating the lumen of the tube a very real one. The operation was certainly easier in the case of tubal pregnancy than in the presence of inflammatory disease; furthermore, as regarded the repetition of ectopic pregnancy, time alone could answer this question. A study of the anatomy of tubal mole had convinced him of the possibility of conservative measures, and he intended to bring the same into practice when the next opportunity offered.

Mr. HICKS read a short communication upon a case of Suppurating Hydropyonephrosis complicating Pregnancy, with remarks upon the symptoms and treatment of pyelitis of pregnancy.—Mr. WHITEHOUSE, in thanking Mr. Hicks for his paper, said that he was glad to note that the author's views regarding the influence of vaccines in this condition coincided with his own. Personally, he had never seen a case which, in his opinion, would not have recovered just as well without vaccines as with them. The majority of patients got well on the usual *régime* of absolute rest, light diet, and urinary antiseptics. Mr. Whitehouse did not agree with Mr. Hicks's suggestion that pressure of the pregnant uterus upon the ureter was the predisposing cause of right side pyelitis, and asked why the right kidney was the organ usually attacked in children? also, why did dilatation of the ureter occur in children and apart from any pressure?—Mr. MARTIN referred to the rapidity with which symptoms of pyelitis were relieved by evacuation of the uterus. If the symptoms did not disappear under ordinary medicinal measures, he always advised evacuation of the uterus in preference to surgical procedures upon the kidney. —The PRESIDENT was also of opinion that evacuation of the uterus was a therapeutical measure of considerable value in some of these cases, although at times it was difficult to come to a conclusion, especially if the fœtus had reached a viable age. In such a case he had sometimes been tempted to advise nephrotomy rather than emptying the uterus.—Dr. PURSLOW thought that many cases of pyelitis were due to ascending infection from the vulva and were to be attributed to lack of cleanliness on the part of the patient.

EDINBURGH OBSTETRICAL SOCIETY.

The Place of Gynæcology in the Medical Curriculum and in General Practice.

A MEETING of this society was held on Dec. 10th, 1913, Sir J. HALLIDAY CROOM, the President, being in the chair.

Dr. A. H. FREELAND BARBOUR read a paper on the Place of Gynæcology in the Medical Curriculum and in General Practice. The Edinburgh Royal Infirmary had, he said, made a noteworthy change i [illegible] the clinical teaching in recognisi [illegible] s a department by itself. Th [illegible] arch, 1906, appointed a lecturer on systematic and clinical gynæcology, distinct from the lectures on midwifery. In May, 1907, an examination on clinical gynæcology was introduced in the final examination, thus coming to stand alongside of clinical medicine and clinical surgery. This did not imply that it was of the same importance as these other two subjects, but it emphasised the fact that no graduate of the University should be allowed to enter the practice of medicine without some evidence of possessing at least an elementary knowledge of this subject. The last [illegible] of 2000 cases in the University gynæcological ward and found that 50 per cent. were referred directly or indirectly to conception or childbirth; 9 per cent. to the want of the menstrual function at puberty; 7 per cent. to the patients entering married life; while 20 per cent. began to suffer late in life towards the menopause. Experience showed that patients of the working and middle classes, who formed the larger proportion of the *clientèle* of the general practitioner, expected to be treated in the first instance by the physician who attended them at their confinements. The examination and diagnosis depended on him, and the routine treatment of chronic cases, what was called minor gynæcology, should be relegated to him. It rested with him to say when the case should pass out of his hands into those of the specialist In the Infirmary, every sixth lecture in the course of clinical lectures was devoted to gynæcology. It might be said that the affections of the reproductive system furnished about that proportion of the work of the general practitioner as far as his female patients were concerned. The intimate relationship of gynæcology with medicine must not be lost sight of. In former days the specialist did not at once enter on his specialty, but took up general medicine as well, and gradually separated himself from that. A wide knowledge of the relation of their own specialty to other departments of medicine and of the features of the individual case for a time under their care gave them a sound judgment which made their opinion weighty. The difficulties which beset the clinical investigation of gynæcological cases had in the past sent the graduate into practice inadequately prepared to deal as efficiently with diseases of the reproductive system as with those of other systems in the female. Unless a graduate had learned as a student in the hospital or dispensary under skilled guidance how to make a bimanual examination, and also what might be learned from it, the little gynæcology he had picked up as a student became less, and finally became a skill or knowledge not possessed. Gynæcology should not be relegated to a post-graduate course; hence there had been given to every student during recent years in Edinburgh an opportunity of learning the elements of gynæcological investigation, and the clinical examination had been introduced into the final examination to ensure that he had availed himself of this advantage. While minor gynæcology would continue to belong to the general practitioner, operative gynæcology had become more and more the work of a specialist. It was on its surgical side that gynæcology had of recent years been specialised. The operating gynæcologist must be prepared to deal with any abdominal condition that might crop up unexpectedly in, or form a necessary part of, an operation on the female pelvic organs. In other aspects of gynæcology there had been a tendency in the opposite direction. In its pathology the idea was current at one time that there was a special pathology of the female pelvic organs which found expression in gynæcological literature such as Bennet's "inflammation of the uterus," and Graily Hewitt's "mechanical, system of uterine pathology." Now the general principles of pathology were applied to pelvic disease. It was recognised that, apart from the peculiarities of the anatomical structures involved and the physiological changes implied in menstruation, there was no difference between salpingitis and appendicitis, and that epithelioma of the cervix did not differ from epithelioma of the lip. The same idea had crept into clinical work and came out in the term "diseases peculiar to women." While the gynæcologist retained his position as a consulting specialist, yet a considerable part of gynæcological practice was being relegated to the general practitioner. It was significant that Kelly, of Baltimore, some years after writing his great work on operative gynæcology, brought out one on what he called medical gynæcology, and in his preface he stated that "this period of surgical evolution is now at last clearly at an end." We seem to be at the beginning of a period of medical evolution. The discovery of the internal secretion of the ovary was making the operator hold his hand in the removal of that organ; the value of organic extracts, thyroid, suprarenal, and pituitary, was becoming recognised, and they were influencing gynæcological treatment; and radium was taking its place in the treatment of cancer.

Dr. D. **Berry Hart** considered gynæcology evolved from obstetrics, as the obstetrician was consulted first. As to whether the gynæcologist should be a surgeon or a physician, the matter had been stated very judiciously. No doubt for a long time gynæcology became a surgical specialty; now they had methods which to a certain extent might supplant that; but he thought that a great proportion of the treatment in gynæcological cases would be of a surgical nature. The general practitioner knew he must be as well trained as possible, and, if so, a greater proportion of cases would come under his care.

Professor H. **Harvey Littlejohn**, Dean of the Medical Faculty, remarked there was no question that gynæcology was a very important branch of medicine for the general practitioner, and that, if possible, every graduate from Edinburgh should have a good working knowledge of it. He gathered that Dr. Barbour considered the teaching at present was insufficient. His feeling with regard to all specialties was that they should get as much time as could possibly be given. They could not turn out men too well trained; unfortunately, there were only five years, and they had to cut the coat according to the cloth. The question was whether more time could be given to specialties, and whether the attendance of students could be systematised at these classes so that they got the maximum of knowledge in the minimum of time. The faculty was considering whether they could not economise in certain directions and give more time to others, so as to improve the training of the student at the end of five years. The students got three weeks' systematic training and 12 hours of clinical work; it was proposed to extend that to 18 hours, and to make it compulsory.

Dr. F. W. N. **Haultain** felt that there had been far too much tendency to separate gynæcology from obstetrics. He thought to separate the theoretical teaching of these two subjects, given by different men, was undesirable. The continuity of the teaching of obstetrics into that of gynæcology was, to his mind, perhaps best. The obstetric physician teaches obstetrics, but he must be a gynæcologist in order to live. If he had enough obstetric cases to keep him he would not have a life worth living. Gynæcology was a specialty as much as that of the eye or ear, and not only so, it was a specialty that was much more difficult to teach, because of want of sufficient material; and if one could not give the students sufficient material to make them thoroughly expert in gynæcology, he thought they had no right to turn them on to the public hall-marked as gynæcologists. Under present conditions the student was either getting too much or too little; that is to say, he was being hall-marked when he passed at the university final because he had passed an examination in gynæcology.

Dr. J. **Haig Ferguson** thought gynæcology might be looked upon from three points of view: the abdominal aspect on surgical gynæcology which was entirely in the hands of the specialist; vaginal gynæcology, which was partly in the hands of the specialist and of the general practitioner; and medical gynæcology which was in the hands of the specialist and general practitioner. The present position of abdominal surgery was mostly due to the operating gynæcologist. The gynæcologist had come in contact and collision with the general surgeon. There was a tendency to encroachment not only in this country but all over the world, except perhaps in Germany. In America it was said that the general surgeon did everything and the gynæcologist risked losing his title and proposed to deal with the abdomen irrespective of sex. He considered the separation of obstetrics and gynæcology as inevitable. In some ways it was to be very much regretted. There was no doubt that a knowledge of obstetrics had been a great help to the gynæcological surgeon especially in regard to diagnosis, and ignorance of obstetrics was certainly a handicap to the general surgeon from a diagnostic point of view. It would be exceedingly unfortunate for obstetrics if obstetricians did not receive training in surgical gynæcology.

Dr. W. **Fordyce** said he had been struck as a teacher and examiner with the difference in the knowledge of the man who had done even a very little gynæcology in the wards and that of the man who had got his learning merely from books. In teaching gynæcology even in the short time available one could do much in the way of helping a man as a general practitioner. A man could learn a great deal in a short course of five or six weeks if it were made compulsory; up to the present time it had been voluntary, and therefore they did not take advantage of their opportunities.

Dr. G. **Keppie Paterson** considered Dr. Barbour's estimate of the proportion of purely gynæcological cases in general practice as too high. With regard to the preparation of a student for general practice, it should be the aim of the curriculum to give the student a primer knowledge of each special subject and how to recognise especially urgent conditions requiring immediate treatment. In gynæcology he should have a course of systematic lectures, and every student should be trained to examine a patient properly.

Dr. G. F. **Barbour Simpson** considered the advances made in recent years had no doubt been due to more careful study by the students and their teachers. Large abdominal tumours no longer came under observation. He could not agree with the opinion that the separation of obstetrics and gynæcology had become inevitable; they could never be divorced.

Dr. **James Young** said it seemed strange that the large amount of out-patient material in the hospital in Edinburgh was not utilised for teaching purposes. In London even the meagre out-patient material which they had in the various hospitals was made use of in the most practical manner.

Dr. H. **Oliphant Nicholson** believed that a man who had followed general practice for many years did very much better work as a specialist than a man who had had no such previous training.

The **President** did not think that gynæcology would ever be absorbed into general surgery. He should be very sorry to see the day when obstetrics and gynæcology were separated. They were two absolutely consolidated subjects. It was, he thought, impossible for any man to discharge the duties properly and take the responsibility of teaching both obstetrics and gynæcology; it was only possible to teach these two subjects by two men who were united in the matter and who taught in relation to one another. He was told it was quite possible for one man to teach both subjects. Well, what did it come to? It came to giving one's work over to assistants, which was nothing like so satisfactory as having it done by senior men.

Dr. **Barbour** replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Exhibition of Cases.—Endocarditis Lenta.

A meeting of this section was held on Dec. 5th, 1913, Dr. J. F. **O'Carroll**, the President, being in the chair.

Dr. H. C. **Drury** showed a man, aged 32, who had Raynaud's Disease. The patient had been in India. Two years ago he was engaged as a night porter. At the beginning of the present winter the disease began in his hands. When first seen four weeks ago his right hand was in a condition of local asphyxia, and the other hand showed commencing gangrene, the whole hand being blue and intensely cold. He never permitted the patient to wash his hands, fearing sepsis. There was no albumin or sugar in the urine, and the Wassermann test had a negative result. The condition came on quite quickly, and its very acute condition was of interest. No pulse could be felt in the left wrist, and in the right it was scarcely perceptible. The patient was treated with alcohol and chloride of calcium, at first with 5-grain doses, and then with 10-grain doses, per diem. There was much pain at the beginning, and opium had to be administered at night. The patient was at work up to six weeks ago. No signs of cardiac disease could be discovered.

Dr. A. R. **Parsons** showed a patient with enormous Dilatation of the Veins on the Abdominal Wall. The man had had typhoid fever in 1893. The onset of very acute pain in the right iliac fossa had caused so much suspicion of perforation that laparotomy was performed. No perforation was found, and the patient made a comparatively uneventful recovery. Two years later he showed signs of obstruction in the two iliac veins, or perhaps in the inferior vena cava. No inconvenience was experienced.

Dr R ATKINSON STONEY showed a patient, aged 41, in a very similar condition to the patient exhibited by Dr Parsons When in South Africa in 1901 he had enteric fever and was in hospital for three months, in bed the whole time, two relapses occurring There was no bleeding from the bowels at any time He was in a convalescent camp for one month During the voyage home he noticed swelling of both legs for the first time most marked in the right leg, which was said to have been 5½ inches larger than normal No enlargement of the veins of the legs was noticed at this time, but the veins on the front of the abdomen were noticed to be enlarging He was in a convalescent home in England for two months, and was then discharged from the army He had since been in the Canadian police force The veins in the legs became enlarged while in that force in 1904 , the enlarged veins in the thigh gave trouble when riding Varicose ulcers first formed on the legs in 1910 , they had healed and broken down twice since then At present there was a very large tortuous vein forming upon each side of the abdomen from below the middle of Poupart s ligaments to the corresponding axilla , the bloodflow was free in both directions , one valve not completely competent was situated just below the level of the nipple There was another large tortuous vein forming upon either side of the middle line from the same origin to the front of the sternum The femoral vein could be felt as a hard cord in each leg up to Poupart's ligament , the abdominal veins had become larger during the last nine months The condition was probably due to occlusion of the iliac veins and the inferior vena cava —Sir JOHN MOORE related a case of his which resembled the two preceding cases, but the dilatation of the superficial abdominal veins was unilateral —The PRESIDENT and Dr T GILLMAN MOORHEAD and Dr W F LAW discussed the condition There was a general feeling that thrombosis of the femoral veins is a commoner sequel of typhoid fever than statistics appear to show

Dr MOORHEAD read a paper on Endocarditis Lenta and showed the organs from a patient who had succumbed to the disease The condition had supervened on a chronic endocarditis The aortic valves became infected after the mitral valves The spleen was enlarged and there was moderate nephritis Streptococcus viridans had been cultivated during life from the blood and recovered also post mortem from the valves —The PRESIDENT thanked Dr Moorhead for his contribution as he considered it a distinct acquisition to know that this definite type of endocarditis had a definite coccus as its recognised cause A point which came into his mind was that when a case came into hospital with an old cardiac lesion there was a proneness to assume that the patient was tired from the effects of his old disease, whereas he might have a new endocarditis —Sir JOHN W MOORE Dr G E NESBITT Dr W M CROFTON, and Dr W D O KELLY discussed the condition

---

SECTION OF OBSTETRICS

Exhibition of Specimens —Eclampsia

A MEETING of this section was held on Dec 12th, 1913, Dr M J GIBSON, the President, being in the chair

Dr GIBBON FITZGIBBON showed a specimen which consisted of the left tube the right ovary, and the uterus The patient was a married woman aged 40 para 2 , five years had elapsed since the last confinement In November, 1912, she was first seen, complaining of profuse metrorrhagia which had been *occurring every fortnight or three weeks* for about three months and lasting 10 to 12 days She was admitted to hospital and curetted for the purpose of diagnosis as possible carcinoma of the uterus At this time the uterus was very little enlarged , the cavity was 3¾ inches with nothing abnormal to be felt in its shape The appendages were apparently normal The patient left hospital in 12 days and when seen two months later the menses had occurred normally twice since the curettage She remained quite well till July, 1913 when she commenced to have pains in the pelvis and abdomen She was not seen again until October, 1913, when she was looking very ill had evidently lost a lot of flesh, and was very anæmic. On examination a tumour was found in the middle line reaching to within one inch of the umbilicus The uterus could not be definitely separated from this tumour, and there was a large mass behind the uterus filling Douglas's pouch and rather fixed, but separate from the tumour in front The condition suggested multiple fibroids except that the front tumour was distinctly cystic At the operation the right ovary was found cystic about the size of a fœtal head and adherent to the fundus of the uterus and intestines This was first removed and then the left tube, which was enlarged to about the size of an elongated cricket ball, was found adherent to Douglas's pouch , when this was removed a hard nodule was found in the bottom of the pouch and connected with the cervix, and as it seemed rather suspicious it was decided to do a hysterectomy This was done as low down as necessary on the vagina to get below the nodule and when the posterior wall of the vagina was divided it was found that the nodule was adherent to the rectum, requiring the removal of a piece of bowel about the size of a shilling The nodule was growing from the cervix extraperitoneally The ovary showed pathologically a carcinoma of a squamous type and rather suggestive of sarcoma The tube was solid and proved to be a columnar carcinoma quite unlike the ovary The nodule on the uterus rather resembled the ovarian cancer The combination of two distinct types of cancer in the tube and ovary at the same time is curious, and the third centre of disease in the uterus resembling the ovarian cancer which was completely removed from the region of the uterine disease, raises the question of the origin—whether the uterine or ovarian condition was primary to the other or were they two independent growths The whole case is of interest from the rapidity of the growth for there was no suggestion of any growth 12 months previously the only suggestion being an early carcinoma of the body of the uterus The patient left hospital in five weeks in better health, but her convalescence was greatly delayed by severe bronchopneumonia and pleurisy, but there is very little hope that the whole disease could have been eradicated —Dr E HASTINGS TWEEDY expressed the opinion that the patient would not have a recurrence for a long period —Sir WILLIAM SMYLY agreed with Dr Tweedy s opinion but suggested that the patient should look out for recurrence in the rectum

The PRESIDENT showed a specimen of Strangulated Pyosalpinx of large size The symptoms developed suddenly, evidently as a result of the sudden strangulation The condition was probably of tuberculous origin

Mr SPENCER SHEILL read notes and observations on several cases including one of Eclampsia —Dr TWEEDY had never been able to see the rationale of bleeding as a treatment for eclampsia It had been suggested that it removed poisons from the blood, but this he considered hypothetical It was mentioned that the patient s urine contained blood, and also that she was passing urine copiously at first , putting these two facts together he suggested that the blood resulted from kidney inflammation the result of concentrated and poisonous urine He submitted that even theoretically there was no reasonable foundation for bleeding unless an equal amount of fluid was put back Saline fluid seemed to him to be the most misplaced thing that could be introduced into the system under such circumstances A salt free diet was considered good for certain inflamed conditions of the kidney, and yet it was suggested in this case deliberately to introduce salt It appeared to him more reasonable to dilute the fluid put into the blood in such a case with carbonate of soda —Sir WILLIAM SMYLY believed in the bleeding treatment for eclampsia It was known that the blood in eclampsia was of high specific gravity and contained less water than usual , that it clots all over the body and that the arterial tension is very high and patients often die from apoplexy Bleeding made the blood thinner and less liable to clot The arterial tension is reduced and apoplexy prevented He considered the great difficulty in knowing anything about the treatment of eclampsia was that even with an enormous number of cases no very definite conclusions could be formed He did not consider that sweating and bleeding were at all the same He looked upon sweating in these cases as bad because it removed fluid from the body when the blood was already too thick —Dr B SOLOMONS spoke of the difficulties in the treatment of eclampsia in private practice There was no doubt that a maternity hospital was the best place for these cases —Dr FITZGIBBON agreed with bleeding in eclampsia if used in suitable cases A large number of cases occur in full blooded women, and such react favourably. The system of introducing saline under the breast had the effect of lowering the specific gravity of the blood.—Mr. Trevor Smith drew attention to the difficulty sometimes of bleeding patients suffering from eclampsia. He recognised that where the right side of the heart was overloaded, bleeding was of the greatest use.—Mr. Sheill, in reply, mentioned that none of the cases of eclampsia he had seen ever suffered from post-partum hæmorrhage. As to the difficulty in getting the blood to flow, he thought once the vein was found this disappeared. He did not agree that the putting of saline in under the breast had the same effect as bleeding, as saline absorbed into the blood might be as rapidly excreted, whereas in the treatment recommended of bleeding, some of the solid matter of the blood was withdrawn and also some of the poisons. He was convinced that the blood in these cases was toxic, and that the removal of some of it would reduce the pressure and also some of the toxins. Altogether he thought that the weight of evidence went to show that bleeding in eclampsia was a good procedure. He considered that an operation performed for sterility had no influence in the development of eclampsia when a pregnancy supervened.

Leeds and West Riding Medico-Chirurgical Society.—A meeting of this society was held on Dec. 12th, 1913, Mr. W. R. Bates, Vice-President, being in the chair. —Mr. J. E. Middlemiss showed a case of Bronchial Asthma, associated with Pregnancy, treated by Hypnotic Suggestion. The patient was a married woman, aged 25, who had suffered from bronchitis since childhood and for the last two years from recurrent attacks of typical bronchial asthma, increasing in frequency and severity, until latterly they occurred once a week or oftener. Her health was much disturbed in consequence. There was almost constant dyspnœa between the attacks. She was unable to walk out alone and unable to assume the recumbent position at night. She had been twice operated on for some nasal or post-nasal obstruction before the asthma began, about five years ago. The patient was first seen in July last during a typical attack of bronchial asthma. She was then six months pregnant and looked very ill and was suffering from chronic laryngitis. The usual medicinal remedies were given and the attack subsided. Suggestive treatment began immediately after. Sittings were given three times a week to begin with, later once a week. She proved readily susceptible to hypnotism at the first sitting. At the second sitting there were complete muscular relaxation and amnesia during sleep. On subsequent occasions first hypnotic suggestions were readily carried out, and the patient conversed without subsequent recollection. Suggestions were given that the attacks would be less violent and less frequent and eventually would cease. Complete cessation of the attacks was insisted upon as treatment advanced. The result was that the patient had been free from asthma up to the present time. Her household duties had been resumed and she was able to lie down flat at night—almost an unprecedented occurrence. The huskiness of the voice did not subside until after some nine weeks of treatment. Labour occurred at term without complication.—Dr. T. Churton showed several cases of Nervous Disease, also cases of Bronchiectasis treated successfully by the Postural Method.—Dr. R. A. Veale showed (1) a case of Spastic Paraplegia in a woman aged 24; (2) a case of Disseminated Sclerosis in a woman aged 29; and (3) some cases of Skin Disease.—Dr. C. W. Vining, in conjunction with Dr. W. H. Maxwell Telling, showed a child, aged 9, with a clinical condition strongly indicating General Paralysis. The symptoms began three months after a blow on the head 20 months ago. The child's general mental condition had changed; he was now destructive, restless, silly, and dirty in his habits The pupils, the reflexes, and the tongue were typical of the condition, and both the blood serum and cerebro-spinal fluid were markedly positive to the Wassermann test.—Dr. Vining also showed a case of Traumatic Neurosis in a man, aged 35, following a fall on the back 18 months ago. The symptoms were hysterical rather than neurasthenic. The objective signs were (*a*) greatly exaggerated reflexes of the limb; (*b*) a coarse tremor of the intention type; (*c*) partial anæsthesia of the palms of the hands; (*d*) a one-sided stamping gait; and (*e*) a reduction in the field of vision of one eye. The main subjective phenomena were headache, insomnia, and loss of confidence.—Cases were also shown by Dr. C. Oldfield, Mr. H. Collinson, Mr. S. W. Daw, Mr. J. A. Coupland, Mr. Alex. D. Sharp, Mr. A. L. Whitehead, Mr. H. Secker Walker, Mr. R. Lawford Knaggs and Dr. G. W. Watson, and Mr. J. F. Dobson.

United Services Medical Society.—A meeting of this society was held on Dec. 11th, 1913, Colonel Bruce M. Skinner, A.M.S., the President, being in the chair.—Surgeon-General Sir Launcelot Gubbins, Director-General of the Army Medical Service, read a most interesting paper on the Life and Work of Jean Dominique, first Baron Larrey. He touched briefly on the early life and education of the subject of his paper, and pointed out that Larrey first joined the navy, but after six months, taking a dislike to the service, retired and returned to Paris in 1789, where he took part in the French Revolution. In 1792 Larrey commenced his long and valuable military career, during which he was present at a great number of engagements. It was during operations around Mayence and Frankfort in 1792 that Larrey was struck by the unsatisfactory methods that existed for dealing with casualties. The plight of the wounded made such an impression on his mind that he conceived the idea of giving them immediate succour. This found expression in the invention of the *ambulance volante* which could keep pace with the fastest battery of artillery. The next important step in Larrey's career was his appointment as professor of surgery and anatomy in the Military School of Medicine at the Val-de-Grâce. In 1797, however, he was ordered to join the army of Italy, and there was brought into official contact with Bonaparte for the first time. Larrey was ordered to make arrangements for tending the sick and wounded, and he organised his *ambulance volant* in three divisions. He was warmly congratulated by Bonaparte on the result of his labours. In 1798 Larrey took part in the campaign in Egypt, and performed a most heroic act in saving a general's life. Larrey's fame was now well established, and he was received with great enthusiasm on his return to Paris. Among other campaigns in which he took a part was that in Russia in 1812, including the historic retreat from Moscow. At Waterloo Larrey was severely wounded by the Prussian cavalry while endeavouring to withdraw his ambulances; he was captured and sentenced to be shot, but was rescued by a Prussian surgeon-major who had attended his lectures years before. He died at the age of 76 at Lyons on his return from Algiers, where he had been on tour of inspection of the hospitals. Sir Launcelot Gubbins contrasted Larrey with his contemporary in the British army, Sir J. McGrigor, Bart., and laid stress on the fact that the former was more of a surgeon than an administrator, while the latter was mainly an administrator.—At the conclusion of the paper a discussion took place in which the following officers participated: Surgeon-General Sir J. Porter, R.N. (retired), the President, Lieutenant-Colonel A. B. Cottell, R.A.M.C., and Major H. A. L. Howell, R.A.M.C.—Sir Launcelot Gubbins having replied, a hearty vote of thanks was accorded him for his paper.

Æsculapian Society.—A meeting of this society was held on Dec. 19th, 1913, Dr. David Ross, the President, being in the chair.—Dr. Harold Mowat read a paper on the Value of Radiography in the Diagnosis of Cases both Surgical and Medical. He described the former method of giving a meal and bismuth before examination by the fluorescent screen, also the method of Dr. A. C. Jordan, the simpler one. Plates of the normal and proptosed stomachs were shown, also one having an irregular outline probably due to old ulceration and adhesions; and of stomachs and intestines at different intervals after the bismuth feed. He also showed several plates demonstrating enlarged bronchial glands, pulmonary tuberculosis, "the hanging heart," and aortic aneurysm. On the fluorescent screen he demonstrated a proptosed stomach in a thin woman and aortic aneurysm in a man aged about 50 years.

London Dermatological Society.—A meeting of this society was held on Dec. 16th, 1913, Dr. Morgan Dockrell, the President, being in the chair.—Clinical cases were shown by Dr. S. Gooding, Dr. J. L. Bunch, the President, Dr. W. Griffith, and Dr. W. K. Sibley. Among Dr Sibley's cases were two of Exfoliative Dermatitis. The first occurred in a man aged 47. There was an infiltration and desquamation of the skin, and from the generalised glandular enlargement he thought the case might be an early stage of mycosis fungoides. In the second, which occurred in a man aged 42, a policeman from India, there was no glandular enlargement, and the condition was rapidly yielding to treatment.—Mr. W. Hampson read a paper on the Dosage of X Rays, the discussion on which was adjourned.

Reviews and Notices of Books.

Digestion and Metabolism: the Physiological and Pathological Chemistry of Nutrition.

By ALONZO ENGLEBERT TAYLOR, M.D., Rush Professor of Physiological Chemistry, University of Pennsylvania, Philadelphia. London: J. and A. Churchill. Pp. 560. Price 18s. net.

THE disorders of digestion and metabolism are so numerous and of such importance practically that a knowledge of the chemical processes concerned is a necessity for the practitioner, in regard both to diagnosis and to the right appreciation of the principles of treatment. Professor Taylor states in his preface that the aim of his book is to describe the chemical changes in normal and abnormal digestion, and to explain the known metabolic modifications that food materials undergo within the body. He presents the present state of our knowledge in regard to these problems in an interesting as well as an original manner. He discusses the results of the application of modern physico-chemical methods to the study of the physiological and pathological chemistry of digestion and metabolism, and he considers the processes concerned dynamically rather than statically. Owing to the advances that have been made the chemical reactions referred to are sometimes complex, and the physico-chemical problems discussed are often intricate, but Professor Taylor writes with such an easy and lucid style that he invariably succeeds in rendering even the more difficult problems intelligible and interesting.

The book is divided into eight chapters, of which the first deals with the composition of foodstuffs. The three natural groups of carbohydrates, fats, and proteins are first considered and their chemical relationships are clearly outlined. The food values of certain raw and cooked foods are then given in tabular form. The second chapter is devoted to a closely reasoned and instructive discussion of the theory of ferment action. Fermentations are regarded as accelerations of existing reactions, and are thus classed with the reactions of catalysis. The chemical reactions of fermentations, the reversal of ferment actions, the nature of ferments, and the modes of their action are all considered at length. The chapter concludes with a discussion of the specificity of ferment action, and taken as a whole is an instructive presentation of a complex and difficult subject. The third chapter deals with digestion, and contains a full description of the various digestive processes, occurring in the mouth, stomach, and intestines. The ferments concerned are all dealt with in detail, and the range of their activity and their mutual reactions are considered. The dynamic method used so effectively by Professor Taylor naturally lends itself to a presentation of the powers of adaptation and compensation in the several functions of digestion, which are shown to be very great. The great importance of the motor functions of the stomach is emphasised, and the relatively secondary rôle played by its digestive functions is clearly shown. The relative importance of the three ferments, pepsin, trypsin, and erepsin, in the cleavage of proteins is worked out. An interesting account is given of the absorption of the products of digestion and of the synthetic processes effected therein by the intestinal epithelium. The fourth chapter is devoted almost entirely to the consideration of the metabolism of carbohydrates, both under normal conditions and in disease. The pathological chemistry of both experimental and human diabetes and the problems connected with it are clearly presented and critically discussed. Professor Taylor uses the terms "glycogenesis" and "glycolysis" when referring to glycogen, and writes of glucolysis and glucosuria when discussing the destruction of glucose and its presence in the urine. In the next two chapters the metabolism of the fats and proteins is considered in the same detailed manner as was that of the carbohydrates. The anabolic and katabolic processes in which they are concerned are clearly discussed so far as our present knowledge permits. In connexion with the fats, the abnormal processes leading to acidosis are described. In the seventh chapter the metabolism of creatin and creatinin, and of purine and phosphorus, is examined. The subject of auto-intoxication is dealt with in a brief chapter, which is highly suggestive in its scientific analysis of this complex problem. A general survey of the problems of metabolism as a whole is given in the ninth chapter, together with a study of some of the abnormalities of nutrition. The concluding chapter is devoted to the discussion of the production of body heat and the regulation of body temperature.

We have nothing but praise for this interesting and suggestive book. It is admirably produced, well printed, and though dealing with abstruse problems is readable and clear.

Blood Pressure from the Clinical Standpoint.

By FRANCIS ASHLEY FAUGHT, M.D., formerly Director of the Laboratory of Clinical Medicine of the Medico-Chirurgical Hospital; Instructor in Medicine at the Medico-Chirurgical College, Philadelphia. London and Philadelphia: W. B. Saunders Company. 1913. Pp. 281. Price 13s.

IN this volume the author has presented in easily accessible form the pith of medical literature bearing on the study of blood pressure in its relation to medicine, not only in cardio-vascular and renal conditions, but also in many diseases in which clinical observation has shown the information obtained by the sphygmomanometer to be of value.

After a brief consideration of the physiology of the circulation, a description is given of the chief forms of the sphygmomanometer now in use and the manner in which they are employed. The auscultatory method is rightly explained at some length, for by its adoption not only the systolic but also the diastolic pressure can be accurately determined, and hence the value of the readings is considerably increased. In order to obtain correct results by this method some practice is required, but when the various "phases" are fully understood, more reliable and more extended information can be obtained than by any other procedure.

The conditions resulting in hypotension are first discussed. It is shown, for example, that in aortic regurgitation a persistent and uniform high systolic pressure combined with an exceptionally low diastolic reading is found, thus yielding a large pulse pressure, and in doubtful cases this is an important diagnostic point. The effects of shock and collapse and of hæmorrhage in lowering the tension receive due attention.

A short chapter is devoted to a consideration of the indications of hypertension when no obvious cause can be discovered. Dr. Faught remarks that hypertension is a subtle condition often lurking where least expected. In accordance with other physicians he is of opinion that a permanent increase in blood pressure in a young adult or in one in early middle life, in the absence of discoverable change in the heart, blood-vessels, or kidneys, is always a sign of a chronic toxæmia; a poisoning probably arising from some error in metabolism or deficiency of elimination, either intestinal or urinary, or both.

The subject of high arterial tension in connexion with arterio-sclerosis and diseases of the kidney is then gone into, and stress is laid on the importance of laying down strict injunctions in regard to diet and the general mode of life which are required. The value of arterial tension in connexion with life assurance has naturally occupied the attention of the medical advisers to the life offices. The introduction of accurate methods of estimating the pressure will doubless lead to further research, but until a large amount of experience has been accumulated, judgment must be suspended. The results published by Dr. J. W. Fisher, of the Northwestern Mutual Life Insurance Company, are quoted, and the tables of mortality records certainly give rise for reflection.

We have perused this volume with much interest; it contains a great deal of interesting information which will be found of value in actual clinical work

---

Practical Bacteriology, Blood Work, and Animal Parasitology, including Bacteriological Keys, Zoological Tables, and Explanatory Clinical Notes.

By E. R. Stitt, A.B., Ph.G., M.D., Medical Inspector, U.S. Navy; Head of Department of Tropical Medicine, U.S. Naval Medical School, &c. Third edition, revised and enlarged, with 4 plates and 106 other illustrations, containing 513 figures. London: H. K. Lewis. 1913. Pp. 408. *Price 6s. 6d. net.*

In our review of the first edition of this work we noted the very practical character of the book and the probability that it would be found to meet the needs of a very large class of practitioners. From the rapid appearance of this, the third, edition it would appear that our prediction has been verified. An important characteristic of the book is its small size. Notwithstanding the considerable additions which have been made in this edition, it has been possible, by a judicious choice of type, to retain this essential feature, and at the same time to give indications of the relative importance of the subject matter. In the bacteriological portion numerous additions have been made which bring the subject up to date, and there has also been a thorough revision of the older material. As with most other works of this character, however, it is in the section on animal parasitology that the largest additions and changes have been required. The number of illustrations has been increased, and the original plate of the ova of intestinal worms which occupied one of the covers of the book has been replaced by excellent drawings, which find a place in the body of the book.

The general scheme remains unaltered, and it still retains as one of its principal features the arrangement of the material in the form of keys, tables, and summaries; additions have been made to these, especially in the section on urine and on intestinal bacteria. New sections have been added dealing with chemical tests of fæces and with disinfectants or insecticides, or, more strictly, with disinfection and destruction of insects. This section will prove very useful and presents the information in the severely practical form characteristic of the book.

The form of the work resembles that of previous editions and is satisfactory, though it suffers from the need to economise space. The book is not so suited to the need of the student as to that of the already trained practitioner. It would be difficult to find a book of so small a size which would prove more useful than this to those whose work is away from books of reference, whose service involves travel and residence in remote districts or in tropical countries.

Pathologische Anatomie. Ein Lehrbuch für Studierende und Aerzte.

Herausgegeben von L. Aschoff, Freiburg i.Br. Dritte Auflage, Erster Band: Allgemeine Aetiologie; allgemeine pathologische Anatomie. Mit 431 grossentheils mehrfarbigen Abbildungen. Zweiter Band: Spezielle pathologische Anatomie. Mit 660 grossentheils mehrfarbigen Abbildungen im Text und 1 lithographischen Tafel. Jena: Gustav Fischer. 1913. Vol. I., pp. 811; Vol. II., pp. 1040. Price M.31.50, Vols. I. and II.

The first edition of this book appeared as recently as 1909, but even a superficial study of the work makes it clear why a third edition should be required in 1913. The editor has been forced to exclude such special subjects as the pathological anatomy of the eye and ear, and the febrile processes. The two volumes deal with pathological morphology, and the author's aim is above all to make this work serve as a bridge connecting pathological physiology with clinical pathology. It has been translated into Italian, and might meet with great acceptance, we think, in an English garb.

The first volume deals with what we may term general pathology, and includes the following subjects: The Internal Causes of Disease, General Pathology of Cells, by R. Rössle (Jena); the External Causes of Disease, by M. Askanazy (Genf); Morphological Malformations, by E. Schwalbe (Rostock); Disturbances of Metabolism, by E. von Gierke; Disturbances of the Circulation, by A. Dietrich (Köln); the Formation of Protective Bodies and Immunity, by R. Kretz (Wien); Inflammation, by O. Lubarsch (Kiel); Pathological Growth, by M. Borst (Munchen). To each chapter is appended a bibliography, and even with the titles of journals and periodicals reduced till identification is most difficult, the list of these abbreviations runs to well over four pages.

Apart from the excellent printing and the scientific merits of the several contributions, there is one fact that stands out very clearly—viz., the exquisite beauty and artistic qualities not only of the illustrations in black and white, but, above all, of the coloured illustrations, which convince by the accuracy of their reproduction. The effects obtained on the surface paper used for text and colour alike far surpass those in some cases relegated to "plates." The illustrations are a triumph in colour printing.

The title of any chapter, such as that by M. Askanazy on the external causes of disease,

gives but a faint idea of the scope of the subject. This chapter alone extends to over 200 pages, is illustrated by over 100 figures, mostly coloured, and includes such subjects as injuries produced by heat, electricity, the pathological effects of light, X rays, changes of barometric pressure, mechanical injuries, chemico-toxic factors, and parasites as causes of disease, including what is known as to vegetable and animal parasites. The article on the general pathology of cells and tissues is both concise and suggestive, and is illustrated by 20 figures. E. Schwalbe's contribution on malformations is a crisp and valuable exposition of the subject, one of which the author is an acknowledged master. Perhaps for those to whom metabolism appeals more strongly t
the essay by E. von Gierk
turbances of metabolism
It is admirably set forth and well illustrated. The description of immunity and allied subjects by R. Kretz, considering the importance of the subject, is none too long. The same author deals with pathological growth, including the whole question of tumours, in a comprehensive manner.

The second volume, on special pathology, follows the usual classification of the pathology of special organs. The editor, L. Aschoff, is responsible for the articles on the heart and pericardium, urinary apparatus, female generative organs, and the digestive system; C. Benda (Berlin) for the blood-vessels; Herm. Schridde (Dortmund) for the hæmapoietic organs and thymus; O. Naegeli (Tübingen) for blood; M. B. Schmidt (Würzburg) for the motor apparatus; H. Beitzke (Lausanne) for the respiratory organs; P. Ernst (Heidelberg) for the nervous system; M. Simmonds (Hamburg) for the male generative organs; C. Sternberg (Brünn) for the liver, gall-bladder, and pancreas; E. von Gierke for the glands with an internal secretion, and L. Jores (Marburg) for the skin.

The coloured illustrations in this volume are also very good. In most of the articles—e.g., that on the heart and blood-vessels—a short description of the normal organ precedes the pathological, and when development is specially important, as in the *a.-v.* bundle of the heart, the importance of knowledge of development is both insisted on and illustrated. Some of the coloured illustrations in Benda's article are not only most artistic, but are reproduced with almost startling realism, more especially to one conversant with the newer methods of histological investigation and staining of sections. In connexion with the literature of the blood-forming organs we failed to find mention of the well-known atlas of Carnegie-Dickson on the red-marrow of bone, nor did we find it in the list of atlases under the head of Diseases of the Blood. The part dealing with the nervous system, even with its necessarily large array of Greek derivations, seems to us not on the same level as some of the other parts, at least as far as illustrations are concerned. The editor's exposition of the urinary apparatus is concise and illuminating. Surgeons might with profit consult the article on the male generative organs, and the same, perhaps even in a stronger degree, might be said as to gynæcologists and the dissertation on the pathology of the female generative organs. The article on internal secretions is well worthy of perusal, as are practically all the others, to which we cannot refer *in extenso*.

In our opinion this is one of the outstanding works dealing with pathological anatomy, both for students and practitioners, not only as regards the value and comprehensiveness of its textual matter, but on account of the vivid presentation in pictorial design of the anatomical and histological facts of pathological morphology.

Malaria: Etiology, Pathology, Diagnosis, Prophylaxis, and Treatment.

By GRAHAM E. HENSON, M.D. With an Introduction by Professor CHARLES C. BASS, Tulane University, New Orleans. London: Henry Kimpton. 1913. Pp. 190, with 27 illustrations. Price 10*s.* 6*d.* net.

IN this work, which it appears was written primarily for the use of general practitioners in malarious districts, Dr. Henson has compressed within the space of 190 pages the main points of so great a subject as malaria. In the introduction Professor Bass expresses his opinion of the author as one well fitted to carry out this difficult task, his experience and researches in respect of the disease for many years in one of the most intensely malarious regions of the United States having enabled him to deal with the subject from the most practical point of view. In eleven chapters Dr. Henson discusses malaria, firstly as to general considerations, then as to the etiology of the disease and the malarial parasites, the malaria-carrying mosquitoes, the other factors concerned in the causation of the malady; the pathology, sequelæ, and prognosis; the diagnosis; the latency, recurrences, and chronicity of the infection; the prophylaxis; and the treatment. The author thinks that the general practitioners in infected areas should regard the eradication of malaria as one of their most sacred duties. The early recognition and proper treatment of the disease are very important in connexion with prophylaxis, and for this reason Dr. Henson, in his book, has directed special attention to the diagnosis and treatment of malaria. Naturally, in a work in which the dealing with so great a subject has been compressed into 190 printed pages, some omissions have been unavoidable, but on the whole the information given is sound as well as practical, and it should prove of much service to those in the malarious districts of the southern portion of the United States, for whom the work was primarily written. A few misprints have occurred; one especially glaring will be found on the dedication page.

Tabular Diagnosis: An Aid to the Rapid Diagnosis of Diseases.

By RALPH WINNINGTON LEFTWICH, M.D. Aberd., late Assistant Physician to the East London Children's Hospital. London: Edward Arnold. 1913. Pp. 359. Price 7*s.* 6*d.* net.

APART from a preface and a brief chapter of introduction this book consists entirely of tables, of which there are in all 350, and an index. Each table occupies one page and is arranged in three parallel columns, of which the first is a list of symptoms, signs, and other clinical features, while the second and third give the character of these in the two diseases or conditions which are contrasted. At the bottom of each table the chief symptoms which the two diseases have in common are briefly stated, and explanatory notes are given of any unusual or special symptom or sign. The author has evidently devoted a good deal of energy to finding and including some of the recently described and little known diagnostic signs which the time of drinking in relation to meals, the use of alcoholic beverages, and so forth. The remarks on this latter subject are indeed judicious and reasonable. We do not think the reason given for discountenancing talking during meals—that it tends to cause bolting the food—adequate. There is a curious, and for those who have no independent knowledge very serious, printer's error on p. 52, where the weights of certain persons' brains are converted into decimals, by substituting a decimal point for the usual comma to separate off the thousands—thus, 2·102 grammes for 2,102 grammes, and so on through the list. Again, under "exercise," when we read of a three hours' walk daily, we wonder for what class of people the authors are writing—a very small one, we fear. An hour at most is the time available for many people who have to earn their living. The tone of the book is optimistic, and there are sound remarks on many subjects, particularly on the injudicious tendency to government by over many hard-and-fast rules, regardless of the unseen conditions of Nature regulating human progress.

The importance of some proper instruction of the young in sex matters is rapidly becoming recognised, and it is in view of this that the "Questions of Sex" Series, published by Cassell and Company, Limited, has come into being. Four volumes of this series lie before us, two for boys and two for girls. In the first of these, *What a Boy Should Know* (1913. Pp. 118. Price 2*s.* 6*d.* net), by Dr. A. T. Schofield and Dr. Percy Vaughan Jackson, information is given concerning sex differences and the generative organs, and the dangers from other boys and grown-up persons, as well as from himself, that menace the unwary youth. In a second of the series, *Before I Wed* (1913. Pp. 130. Price 2*s.* 6*d.* net), Sir Thomas Clouston discusses the physiology and psychology of the sex principle, the relation thereto of literature and art, the importance of heredity, health, eugenics and home, and so forth.——For girls also it is becoming realised that knowledge, not the innocence of ignorance, is the best armour against the temptations of after-life. In *Life and its Beginnings* (same series. 1913. Pp. 137. Price 2*s.* 6*d.* net), Dr. Helen Webb gives to mothers a charming little volume which they may fearlessly put into the hands of their children under 12. There is no reason why, as announced on the cover, it should only be "for girls under 12." A companion book for girls over 12 is *From Girlhood to Womanhood* (same series. 1913. Pp. 142. Price 2*s.* 6*d.* net), by Dr. Elizabeth Sloan Chesser. She does not confine her information and advice to matters physical, but has excellent chapters on the cultivation of enthusiasm, girls' loves and friendships, and the necessity of work to insure happiness in life. These volumes would have been of more widespread use had they been issued in a less expensive form.

A fourth volume, entitled *Youth* (London: Charles H. Kelly. 1913. Pp. 151. Price 1*s.* net, cloth boards 1*s.* 6*d.*), has now been added to the three "National Health Manuals," edited by Dr. T. N. Kelynack. This series is intended to prove of use in connexion with various social service undertakings. As the editor rightly points out in the preface to the present book, we are still in the experimental stage in regard to most matters relating to so-called social reforms, so that in order that we may not be led into serious error, through deficiencies or extravagancies, it is essential that scientific principles should be fully grasped and followed as the chart and compass of all attempted social progress. In the present volume various contributors deal with different topics. After an introduction by the editor, Sir James Crichton-Browne discusses growth and development in youth, Sir Thomas Clouston the psychology of youth, Mrs. Alice M. Burn, M.B., the hygiene of the adolescent girl, Dr. Athelstane I. Simey that of the adolescent boy, Dr. Robert Hutchison the diet of youth, Dr. John Lambert the occupations and recreations of youth, Dr. J. M. Fortescue-Brickdale the disorders of youth, Dr. Allan Warner education and youth, Sir Alfred Pearce Gould habits and youth, Professor James Alexander Lindsay the ethics of youth, and Dr. Robert Murray Leslie youth and citizenship.

Nerves (London: Williams and Norgate. 1913. Pp. 256. Price 1*s* net), by Dr. David Fraser Harris, Professor of Physiology in the Dalhousie University, Halifax, N S., is one of the useful series of volumes published under the general title of the "Home University Library." It is neither a physiological nor a psychological manual, but confines itself to an exposition, in phraseology as little technical as the nature of the subject will permit, of "the capabilities and peculiarities of the nervous system, more particularly of those regions whose activities are not associated with the rousing of consciousness." The general construction of the nervous system is indicated, and the mode of transmission of impulses, reflex action, coördination, the mutual coöperation of nerve impulses, fatigue and repair, sleep, and so forth, are plainly described. A glossary, a bibliography, and an index are appended.——The wisdom of the ancients is a fount from which all who will may lawfully draw their inspiration. When, on turning to the end of Dr. George Lincoln Watson's *Calm Yourself* (Boston and New York: Houghton Mifflin Company. 1913 Pp. 46. Price ·50 cents), one reads that the Emperor Antoninus Pius left the most effective monument to himself "when, after composing himself for his last sleep, he gave to a servant the watchword he had chosen for the night: Equanimity," one is irresistibly reminded of Osler's classical valedictory address at the University of Pennsylvania, which ends: "Gentlemen, Farewell, and take with you into the struggle the watchword of the good old Roman—*Aequanimitas.*" But similar as are the endings and identical as is the subject matter, this address by Dr. Watson at the Harvard Medical School treats the theme in an altogether different manner. It breathes the spirit of the practitioner rather than of the philosopher; it is a clinical lecture rather than an academic exhortation. He points out how much of the unpleasantness of life is due to traditional association—e.g., "tired and cross," as though the two things were necessarily bound up together. "Go home," he says, "after a hard day's work and say, 'Why tired and cross? Why not tired and good-natured?'" There is undoubtedly a great deal in that. Other maxims he gives, which can be varied *ad lib.*, for use under diverse conditions of disturbed mental equilibrium. The book would be a useful little manual of self-help for the timorous, the fretful, and the querulous.

JOURNALS AND MAGAZINES.

The American Journal of Tropical Diseases and Preventive Medicine. Vol. I., No. 4.—This journal, the official organ of the American Society of Tropical Medicine, is edited by Dr. Creighton Wellman, and published monthly at New Orleans, in which city the Tulane University of Louisiana, with a School of Hygiene and Tropical Medicine, is situated. The number before us contains a large amount of useful and interesting information. The first article is supplied by the editor, in conjunction with Dr. Howard D. King, and gives a list of all the varieties of mosquito reported as being found in New Orleans. Dr. Allen J. Smith and Dr. Oswald E. Denning describe a curious instance of a Worm, Agamomermis Restiformis, found in the urethra of a man from North Carolina. An informing article upon the Proper Diet in the Tropics, with some pertinent remarks on the use of alcohol, is contributed by Dr. Allan C. Eustis, of the School of Hygiene and Tropical Medicine, Tulane University. Dr. Eustis lays particular stress upon the dangers of a meat diet in the tropics. On the other hand, he sees no physiological reason why an occasional alcoholic drink will cause harm, but this practice if persisted in will give rise to overtaxing of the body "with a poison which the liver is taxed to oxidise in a climate in which there is no indication for same." The editor, in collaboration with Dr. Eustis and Dr. Leonard C. Scott, supplies a paper on the Rapid Cure of Polyneuritis Gallinarum by Intramuscular Injection of a Substance Isolated from Rice, with a note on the pathology of the disease. Dr. Alfred Moore contributes a report, with illustrations, of a case treated by him in the wards of St. Joseph's Hospital, suffering from Hookworm Disease, in which a remarkable amount of emaciation was observed. A very important bacteriological study of the Water-supply of New Orleans is furnished by Dr. Charles Louis Jacob. The supply is taken from the river Mississippi, and since 1901 it has been purified by the use of rapid mechanical filters, sulphate of alumina being the coagulant employed. Apparently there has been a continued prevalence of enteric fever in this city for a number of years, but contrary to expectation the introduction of the water purification plant in 1901 was not followed by any diminution of the prevalence. Dr. Scott regards the river as a polluted source of supply, and the amount of existing pollution is likely to go on increasing. Nevertheless, the effluent of the town filters is of "good sanitary quality." New Orleans, like many cities in the Southern States, is burdened with a large negro population, whose filthy habits and liability to the infection of enteric fever are well known. In the *Journal* are given also a number of short annotations by the editor on matters of interest, such as cholera in the Balkans, and sanitation and tropical agriculture.. News and comments, along with a review of current literature on tropical diseases and hygiene, complete the contents of a very readable number.

The Eugenics Review (London: Eugenics Education Society. Quarterly. Price 4*s.* 8*d.* per annum, or single copies 1*s.* 2*d.*) contains in its latest number the address on Eugenics of War, delivered by Dr. David Starr Jordan, Chancellor of Stanford University, U.S.A., at Sunderland House last July, in which the view of war as contributing to the virility of the human race is combated. A Criticism of Eugenics, by A. M. Carr-Saunders, which asserts that although many of the opinions usually held by eugenists may be capable of justification, such justification is at present lacking. In Depopulation and Eugenics (to be continued) Lucien March essays to show that first-born children are more susceptible to hereditary taints, and that last-born more frequently find a place among the distinguished members of society, while Sören Hansen endeavours to demonstrate the inferior quality of first-born children, not only at birth but as persistent in later life.

The Child (London: John Bale, Sons, and Danielsson, Limited. Price 21*s.* per annum; single copies 2*s* net). edited by Dr. T. N. KELYNACK, contains in its December issue an interesting account of the School Child in Japan, by Dr. Yasusaburo Takaki; Eurhythmics and Child Welfare, by Percy B. Ingram, which advocates the Dalcroze system of eurhythmics and contains some very Greek-looking pictures; the Legal Custody of Children, by A. E. Stanley Smith; Child Welfare in the United States of America, by Robert J. Parr; Child Welfare and the Responsibilities of Central Authorities, by F. E Fremantle, F.R C.S., F.R.C.P.; Baby Talk and School Speech, by Professor Walter Rippmann, M.A.; a Biographical Notice (with portrait) of Dr. Abraham Jacobi, of New York, "a pioneer and benefactor of child welfare," by Francis Huber, M D., B.S.; the Tuberculosis Preventorium for Children, by Alfred Hess, M.D.; and a paper on the Edinburgh Cripple and Invalid Children's Aid Society, by Miss C. Allan Dow.

KING'S COLLEGE, LONDON: LISTER MEMORIAL.—A tablet to the memory of Lord Lister will be unveiled in King's College, London, by Lord Rayleigh, Chancellor of the University of Cambridge, on Wednesday, Jan. 14th, at 4.30 P.M.

NATIONAL ASSOCIATION FOR THE PREVENTION OF INFANT MORTALITY.—A post-graduate course of lectures on the Feeding and Care of Infants, with Special Reference to the Milk Problem, will be given under the auspices of the above association on successive week-days from Jan. 12th to 22nd at various places in London. The lecture hour will be 10 A.M. and 8 P.M, with additional lecturers in the afternoon or visits to nursery training schools, schools for mothers, or similar institutions. On Jan. 12th, at 5 P.M., Professor G. F. Still will give the introductory address of the course at the Royal Society of Medicine, 1, Wimpole-street, his subject being Preventive Methods in Relation to Infant Mortality. Other lecturers include Dr. H. C. Cameron, Dr. E. Cautley, Dr. David Forsyth, Dr. Major Greenwood, jun. Professor A. Harden, Professor H. R. Kenwood, Dr. A. E. Naish, Dr. Eric Pritchard, Dr. John Robertson, Dr. Amand Routh, Dr. Harold Walker, and Dr. Mackenzie Wallis. The complete course is intended for medical men at an inclusive fee of £1 1*s.*, but the course of evening lectures and certain of the other lectures, including the introductory address, are open to non-medical persons on payment of 5*s.* or 10*s.* respectively. As far as accommodation will permit, infant consultations on Thursday afternoon can be attended by non-medical persons. Full particulars can be obtained from the secretary at 4, Tavistock-square, London, W.C., to whom all fees are payable. It is requested that application for tickets should be made immediately.

# Reports and Analytical Records
FROM
THE LANCET LABORATORY.

DIA-PARAFFIN.

(THE SACCHARIN CORPORATION, LIMITED, 10, ARTHUR-STREET, LONDON, E.C.)

ACCORDING to our analysis this preparation yields 28·20 per cent. of liquid petroleum when extracted with ether, and yet dia-paraffin is a light-coloured crystalline powder. It is a combination of diamalt, a crystalline and exceedingly active extract of malt, with paraffinum liquidum B.P. The preparation shows a powerful digestive action upon starch. With water it forms an emulsion which in appearance resembles milk, and in that form it is convenient to take, the malty flavour rendering it quite palatable. Altogether dia-paraffin affords an excellent way of taking the bland hydrocarbon oil for the purpose of a laxative, while of course it possesses also nutrient and digestive properties.

ACITRIN.

(THE BAYER COMPANY, LIMITED, 19, ST. DUNSTAN'S-HILL, LONDON, E.C.)

Of the derivatives of phenyl-cinchoninic acid which have been employed in the treatment of gout, the ethyl ester, or, as it is conveniently called, acitrin, appears to give the most satisfactory results. Acitrin leads to an increased elimination of uric acid, which, however, does not commence as early as when free phenyl-cinchoninic acid is used. Experiments are cited which show that on an average after the administration of 7½ grains four times a day the daily excretion of uric acid rose from 0·75 gramme to 1·237 grammes. It is a tasteless and odourless pale yellow crystalline powder. Its action is said to be gentle, so that the elimination of uric acid is not too rapid, in which case renal colic may be set up.

(1) "TABLOID" THREE GLANDS; (2) "VAPOROLE" TINCTURE OF IODINE.

(MESSRS. BURROUGHS WELLCOME AND CO., SNOW HILL-BUILDINGS, LONDON, E.C.)

(1) The tabloid three glands present the thyroid, suprarenal, and pituitary elements in the proportions normally contained in the body, and their administration is suggested in cases in which it is assumed that the degeneration of these glands respectively is responsible for the increased liability to tumour after middle age. The existence of an interglandular relationship between these three glands appears to have been established, and the suggestion is that they coöperate in governing cell activity. A case is quoted in which carcinoma of the pharynx was treated with "three glands." After two months' treatment there was a decided increase in the weight of the patient, while an augmented dose resulted in improved deglutition. The glands yielded on analysis a definite amount of iodine. Each tabloid contains 6 grains of thyroid gland, ¾ grain of suprarenal, and 1/16th grain pituitary. (2) A 3 per cent. tincture of iodine contained in a hermetically sealed tube offers an obviously convenient method when employing the tincture as an effective and non-toxic germicide. The "vaporole" is issued in two sizes, one containing 20 minims of tincture and the other half a fluid ounce. The point of the container is wrapped in a swab of absorbent material. In this way when the

LONDON: SATURDAY, JANUARY 3, 1914.

Humanism and Medicine.

THE beginning of a New Year forms for all thinking people a convenient place in the calendar at which to register their experiences of the past and to form plans for the future; but such revisions and provisions, to have full value, should not be too limited, for any tendency to regard the separate years as isolated periods rather than as artificial divisions of continuous time, betrays us into an exultation or depression of spirits neither of which may be warranted by fuller consideration. No one can deny that the calling of medicine in this country is passing through a very anxious phase, and while certain of the changes that have recently been brought about in our professional life are very commendable, there are others which are repugnant to the better feelings of many, and some which may yet be found of most unfortunate tendency. It is absolutely necessary to regard the legislation for national insurance against sickness and its results as a phase in a consecutive story—the story of the development of medical practice; we may deplore the machinery inflicted upon that development—and some here even go so far as to speak of retrogression—but we have to own that the legislation followed upon a wider understanding by the public of the essential part that medicine must play in social reform. No separation between panel practice and other medical practice is possible in the minds of those who take this larger survey. They will see in panel practice an expression of the desire of the people to enjoy the ministrations of medicine in a fuller measure; they will know that the truths of medicine are the same however disseminated; and they will be inspired by a certain hope that experience, and the same anxiety for scientific assistance which led to the new legislation, will also lead to the perfecting of the laws to any extent that may be found necessary. The outlook for 1914 is not one of gloom. The public demand made upon medicine, upon every branch, section, and division of our calling, is that we should assist in the improvement of the social, moral, and physical conditions of the State. In our response we must use such legislation as is fitted, and must work for any innovations or reforms that are found necessary. So will the story from year to year be one of progress.

It is a remarkable testimony to the influential evolution of medicine that well-nigh day by day a medical side to all things makes its appearance, compelling from intelligent people a recognition of the spread of our science. The recognition is as good for medicine as it is for the world at large, for medicine is essentially one of the branches of human learning that require the coöperation of humanity in their development. And this diffused interest in medicine has to our minds a close parallel. The humanists during the great Renaissance of the sixteenth century estimated and distributed the stores of classical literature placed at the disposal of the world by the revival of learning, seeing in them the food and instruction necessary for a vast journey forward in civilisation. The efforts of the humanists were all in favour of social betterment, and although nothing was more foreign to their declared objects, and nothing more hidden from the leaders of that superabundant artistic movement, they were heralding the abolition of the rampant constitutional and religious abuses of the day. Something of the sort has been taking place in the educated world of late, where the essential truths of medical doctrine have been receiving an increasingly wide appreciation; and it is reasonable to suppose that the time may be close at hand when every educated person will have his grounding in natural philosophy, as every educated person, from the days soon after the Renaissance until the latter half of the nineteenth century, was supposed to be well read in the classic literature of Greece and Rome. To-day a familiarity with *litteræ humaniores* is not a proof of learning; it is recognised alike that some who possess this familiarity are in no sense intellectual leaders, and that many whose classical equipment is negligible or absent are the forceful spirits among us—the most alive to what is taking place in the world of affairs, and the most prescient as to probable sociological developments. This is not said with any idea of belittling what the study of the classic authors has done for the world. At no time did it make a great number of classical scholars, but it has to be recollected that no such intention was ever formulated by anybody. The erection of a knowledge of classics into a career, other than for the professors of the various subjects, was not contemplated deliberately; the fact that our judges and our bishops, many of them, and that our legislators in a still larger proportion, were the men who in their youth had excelled in scholarship was an acknowledgment following the implied teaching of the Renaissance that on a foundation supplied by Greece and Rome would civilisation best expand. It was therefore natural that those who aspired to take a prominent part in the expansion should know how those foundations were laid. The classics were cultivated because with the revelation of the wisdom, splendour and humour enshrined therein, there grew up a conviction that herein was given a general instruction in the affairs of life which could be assimilated in conjunction with, or as supplemental to, the teachings of religion. In our country this conviction was well-nigh unchallenged until the beginning of the Victorian era, but during the past half century the general mental attitude has perforce greatly changed. The various developments of civilisation have made a call upon students for specialised intelligence in directions where classical equipment has but a secondary use. There will always be room for the great scholars, and it is essential that the world should not lose the value of the lessons taught by classical study. But many of our students never became classical scholars, when it was believed that in this direction lay the best practical equipment; now that we believe otherwise it has become unreasonable to press classical learning, in any but a rudimentary form, upon the bulk of them. For many the classical education remains valuable because the framework of their professional studies is of a classical pattern; but to-day the subjects in which the public instinctively seeks instruction are those of natural philosophy. And as in response to increasing sentiment in this direction a scientific education becomes the equipment of more cultivated men, a prospect is opened up for medicine sufficiently splendid to dispel any temporary depression. No greater stimulus can scientific medicine receive than the coöperation of an enlightened public.

The spread of learning among civilised nations is now and certainly taking more and more the form of scientific instruction, and we may expect the same sequence of events as followed the rise of general classical learning. The Renaissance opened the minds of men to take a more comprehensive view of life, and stimulated among them a demand for responsible government, a respect for expert advice, and an unwillingness to swallow as incontrovertible truths things which depended only on deformed traditions. And thus will education in the principles of natural philosophy act. There will be no plethora of men of science, just as under the old *régime* there has been no plethora of classical scholars. But the learning instilled will be of more direct use to a larger number of students, and it will inevitably follow that the principles of medicine, whose transformation in so many directions into an accurate science, or blend of sciences, proceeds apace, will become familiar to the well-instructed classes. From this time forward the world will become a better and a happier place, for true medicine must ever be found on the side of peaceful reform. Already we have seen political annexation made effective by the teachings of medicine; wars are entered upon with a heavier heart now that rulers and counsellors know that the conditions of warfare are such as to defy the principles of common humanity as indicated by our science; pathological studies have altered practical geography by their assistance to the canalisation of Panama; and social reform in all the nations is one long application of the teachings of hygiene, whether directed towards eugenics, the promotion of education, or the abolition of poverty and disease. We are assisting in an age of boundless promise for scientific medicine. The stirring reflection is needed for our support during a period of considerable unrest.

◆

Calcutta's Health Problems.

THE report which the Acting Health Officer of Calcutta has prepared on the health of that city for the year 1912 is a remarkably complete and interesting volume, which contains, in addition to much detail of an enlightening character, diagrams and graphic illustrations which serve at a glance to demonstrate the points which it is desired to urge upon the attention of the reader. These points are of the greatest topical interest, though the facts which illustrate them are more than a twelvemonth old.

The death-rate of Calcutta for 1912—namely, 28·1 per 1000—was slightly higher than that of 1911, but compared with the mean ratio of deaths per 1000 during the previous five years, which was 34·5, it gives most satisfactory evidence of the gradual improvement which has been made in the sanitary condition of the city. But the point brought out to which we would call attention is the mortality amongst females. This reached the high figure of 36 per 1000, against 23·9 per 1000 in the case of males, figures in striking contrast to the almost universal experience in European countries, but remarkably similar to that described quite recently by our correspondent in Constantinople. This being so, it is interesting to consider the causes. "One of the principal causes of this terrible mortality," says the report, "is almost certainly the custom of secluding the women of the house in the Zenana. In order to secure privacy at all costs the ventilation and lighting of the minor portions of the house are too frequently neglected." India and Turkey are here in a like case. The effect of these conditions is reflected in the excessive prevalence of pulmonary tuberculosis amongst females. In Calcutta twice as many more females than males die from that disease every year. In this connexion it is disappointing to learn that the proposal to establish a Calcutta tuberculosis establishment was postponed for a year. Apart from the question of its use as a means of treating suitable cases a tuberculosis dispensary can be made an educational institution of great value. It should teach the value of fresh air, the danger of spitting, and other simple rules, the effect of which, like that of most beneficial teaching, would radiate far beyond those immediately affected. Much can be done here, too, by the sympathetic cooperation of enlightened women. Speaking of the work done by the female sanitary inspector, the report urges the necessity of a large staff of "health visitors"—at least one for each district of the city. "Some day we may see the educated Bengali ladies visiting their poorer sisters in the bustees and giving them simple lessons in hygiene." No work which women who desire to advance their race can undertake could, we think, exceed this in result, as helping to remove the superstition and ignorance of their poorer sisters.

Such work also would go far to reduce the enormous amount of preventable infant mortality, the details of which form so depressing a feature in the report. During 1912 5044 deaths occurred among infants in Calcutta, giving the high rate of 259 per 1000, yet even so the outlook, says the report, is distinctly encouraging when the records of the last 20 years are considered. This, we think, only serves to show the immensity of the problem and the great scope for improvement. For so much of this mortality is due to preventable causes. Out of the total number of 5044 deaths, 1845 died before they were a week old—that is to say, that 36·5 per cent. of the total infantile mortality occurred during the first week of life. That is sufficiently deplorable, but still more deplorable is the fact that 33 per cent. of the deaths among infants under one month is preventable. "Such a state of things ought not to be tolerated in any civilised community," says the medical officer, and few, we think, will be found to disagree with him. It is a condition of affairs which calls for immediate attention, but what do we find? Most of these deaths are due to improper treatment at childbirth. The Calcutta corporation employs four midwives, and excellent results have attended their efforts to reduce the fearfully high mortality, yet proposals to increase the number of midwives have been negatived. It is astonishing, we should say it is incredible, that such indifference to the loss of human life and to human suffering could exist did we not know of many other municipal instances where finance has been considered before lives. In this connexion much might be done by enlightened Indian ladies visiting and instructing their poorer neighbours, and we applaud the movement that is taking place in this direction. Other reforms also are foreshadowed, and perusal of the latest official account of the public health of one of our most important capitals leaves us with the gratifying certainty that the affairs of the British Empire are being carried on with a great regard for the principles of public health. May this spirit remain and progress, for in this way do we, as an Empire, justify our wide-ranging rule.

◆

Progress of State-aided Treatment for Cases of Tuberculosis.

SOME useful particulars of the provision made by public authorities in England for the treatment of tuberculosis are contained in the Public Health and Local Administration Section of the Annual Report of the Local Government Board for 1912–13, which has now been issued.[1] This department is charged with distribution of grants in aid to local authorities for tuberculosis treatment, some for current expenses of "maintenance," and others for capital expenditure on the provision of institutions. For the latter a fixed sum of £1,116,156 was made available in England under the Finance Act, 1911. Up to August 30th, 1913, the latest period covered by the report, only some £13,400 had actually been paid, but in many cases buildings are in progress towards which grants are being made in instalments. At the date mentioned, also, plans had been submitted to the central office by local authorities for the provision of nearly 3000 additional beds in institutions for the treatment of tuberculosis, while many authorities had plans in preparation for the provision of new institutions or for additional accommodation in existing institutions. In the case of capital grants made for hospitals, dispensaries, or other institutions belonging to bodies other than local authorities, the Local Government Board requires an agreement that the institution should be handed over to the local authority free of debt in the event of the governing body failing to maintain it in a manner approved by the Board.

As regards the cost of maintaining "institutional treatment of tuberculosis"—a term which appears to include dispensary treatment as well as that given in sanatoriums and hospitals—the report estimates that a main dispensary with its branches for every 100,000 of the population should cost about £1000 per annum, or 2·4*d.* per head of the population. Sanatorium or hospital beds, on the scale of 1 for every 5000 of the population and at 30*s.* per week for sanatorium beds and 27*s.* 6*d.* per week for hospital beds, should represent a further annual cost of about 7·1*d.* per head of the population for "residential" treatment. The gross annual cost of a complete local scheme is on this reckoning about 9·5*d.* per head of the population. Towards this, in the case of the insured, the repayment possible from insurance funds is about 8*d.* per insured person. The deficit has to be added to the cost of treating non-insured tuberculous cases, the total forming a charge on each local area, of which Government funds bear a half, if the Local Government Board is satisfied with the local arrangements.

The report states that up to August 30th local schemes for tuberculosis treatment had been submitted which relate to over 75 per cent. of the population of England. What are termed "complete" schemes of institutional treatment had been prepared by 34 out of the 50 English county councils and by 50 out of 72 English county borough councils. Approval had been given to the appointment of 108 "tuberculosis officers," 63 in counties and 45 in county boroughs. In nine of the cases the approved tuberculosis officer is also the local medical officer of health, but the report indicates that this arrangement must necessarily be exceptional. The ordinary function of the medical officer of health in the matter lies in executive and organising, and not in clinical work. The tuberculosis officers referred to are those engaged in dispensary, domiciliary, or consultative work, and do not include, as a rule, medical officers of sanatoriums or special institutions for tuberculosis, although some of them may have charge of tuberculosis beds in local hospitals. The report gives the total number of hospitals which the department has approved, temporarily or otherwise, for the treatment of tuberculosis as 211, of which 15 sanatoriums and 87 isolation hospitals are institutions provided by local authorities, and 88 sanatoriums and 21 general hospitals are provided by voluntary bodies. The number of beds thus provided by local authorities up to August 30th was 3397, and by voluntary bodies 4016. In regard to London, the report gives special consideration to the rather bewildering negotiations and arrangements with which the Local Government Board and the numerous administrative bodies concerned have so far been occupied.

Annotations.

"Ne quid nimis."

THE NEW YEAR HONOURS.

The medical names appearing in the list of recipients of New Year Honours are not very numerous, and attention might be called to one or two omissions; but all the men selected for distinction, to whose services it is our pleasure to call attention, may be congratulated upon having thoroughly earned their titular rewards. Sir Christopher Nixon, a former President of the Royal College of Physicians of Ireland, and one of the most prominent members of the medical profession in that country, is to be sworn of the Irish Privy Council. Sir Thomas Joseph Stafford, the only new medical baronet, is the Medical Commissioner of the Local Government Board in Ireland. Knighthoods have been bestowed upon Surgeon-General A. T. Sloggett, R.A.M.C., Director-General of the Army Medical Service; Dr. T. B. Nariman, of Bombay, physician to the Parsi Lying-in Hospital in that city; and Dr. Harry Brookes Allen, professor of pathology and Dean of the Faculty of Medicine in the University of Melbourne. In the Royal Victorian Order Sir Rickman Godlee, President of the Royal College of Surgeons of England, and Sir William Job Collins, who has been a prominent Member of Parliament, Vice-Chancellor of the University of London, and chairman of the London County Council, receive the Knight Commandership. Major James Currie Robertson, I.M.S., Sanitary Commissioner with the Government of India, has been appointed C.I.E. Surgeon-General Harold George Hathaway, Deputy Director of Medical Services in India, receives a C.B. The Kaisar-i-Hind Gold Medal for Public Service in India has been awarded to Dr. William Stokes, chief of the Medical Mission Hospital at Calicut; Dr. Marcus B. Carleton, in charge of the Leper Hospital at Subathu; and Dr. James Shepherd, also in holy orders, in charge of the Medical Mission at Udaipur. Sir Arnold Theiler, who has been appointed K.C.M.G., is the Director of Veterinary Research in the South African Agricultural Department; and Major J. D. E. Holmes, D.Sc., who is appointed C.I.E., is the bacteriologist in charge of the Imperial Veterinary Laboratory at Muktsar. Among other recipients of honours we may also mention Sir James Thomas, who built and equipped the Cardiff Medical School, and Sir Robert Blair, education officer of the London County Council, who have received knighthoods; and the Rev. Paul Wagner, superintendent of the Leper Asylum at Orisa, who has received the Kaisar-i-Hind Gold Medal. Surgeon-General Arthur William May, C.B., Director-General of the Medical Department of the Navy, has been appointed honorary physician to the King. The editor of *Punch*, scholar and man of letters as well as a great humorist, Mr. Owen Seaman, has been knighted. To all these we beg to offer the congratulations of the medical profession upon their well-deserved distinctions.

OUR POET LAUREATE.

The medical profession will always have a proprietary pride in Dr. Robert Bridges as a Poet Laureate who has been a practising physician. In primitive communities the tribal bards, who were the forerunners of Poets Laureate, exercised the functions of a medical man in that they treated wounds and illnesses by incantations—i.e., by charms (carmina) recited over the sick man. In the twelfth–thirteenth century Gilles de Corbeille showed that a medical man could also write almost classical Latin verse, and in later years the medical profession can number among authors of verse, if not of poetry, Blackmore and Garth, the latter of whom in "The Dispensary" held up the former to ridicule by quoting pompous balderdash from his "King Arthur." Another medical verse writer was Akenside, who in his youth wrote at least one charming poem, "The Pleasures of Imagination," and yet another was Armstrong, who composed a didactic treatise in verse called "The Art of Preserving Health," and was not very inspiring in the result. But even Lucretius, we imagine, would have failed to make the processes of digestion poetical. Armstrong certainly did not succeed. He seems to have been impressed by the "dura ilia messorum," for in Book II. he says:—

> "Nothing so foreign but th' athletic hind
> Can labour into blood. . . .
> His daily labour thaws
> To friendly chyle the most rebellious mass
> That salt can harden, or the smoke of years;
> Nor does his gorge the luscious bacon rue."

But in the present holder of the ancient and honourable office of Laureate we have one who is not only a skilled physician but a very real poet, and his virtues and versatility have recently been set forth by a brother poet, Dr. T. H. Warren, the professor of poetry in the University of Oxford.[1] Dr. Warren's lecture is in no way a critique of Dr. Bridges's art, but a graceful introduction to and mention of his work. It is pleasing to see the head of a house and a professor who can descend from the Olympian heights, where all heads of houses dwell, to make jokes, and Dr. Warren's wicked perversion of the Vincentian canon *apropos* of Dr. Bridges's shrinking from the "popularis aura" is happily conceived, and we are sure that the professor of poetry, who is himself a finished scholar, must have welcomed with joy the witty allusion to the new Poet Laureate's skill in writing triolets, "Nectera at hoc tria olet," which appeared in the current epilogue to the Westminster Play, as well as the allusion to the new prosody. Besides various extracts from Dr. Bridges's English poems, including, we are glad to see, the "Elegy on a Lady whom Grief for the Death of Her Betrothed Killed," which recalls the best work of Herrick and Spenser, Dr. Warren mentions the clever and almost unknown "Carmen Elegiacum de Nosocomio Scti Bartholomaei," published in 1877. This was an account of the hospital and its staff. Another work to which Dr. Warren refers is the delightful account of the casualty department given by Dr. Bridges from personal experience in the St. Bartholomew's Hospital Reports for 1878. This is written in the gravely ironical style, the secret of which the cultivated physician would appear to possess almost more than the members of any other profession. To pass to another side of Dr. Bridges's art, the professor of poetry recalls his knowledge of and love for music as exemplified in the Yattendon Hymnal, a work which is far less known than it should be, both on account of the beauty of the hymns selected or written by Dr. Bridges himself, and also for the magnificent and dignified tunes. The whole medical profession is proud of Dr. Bridges, and we may add owes a debt of gratitude to Dr. Warren for this charming tribute.

THE MEDICAL STAFF OF THE METROPOLITAN ASYLUMS BOARD.

ON the question of the salary to be attached to the position of medical superintendent of Darenth Industrial Colony, made vacant by the appointment of Dr. Arthur Rotherham as one of the Commissioners under the Mental Deficiency Act, and the method of filling the position, the Asylums Committee of the Metropolitan Asylums Board presented a report dealing with the whole question of the relations of the Board with its medical staff. The committee in this report did not see how the Board, in respect of the position at Darenth, could increase the maximum to be offered to an individual, at present unknown, beyond that which, only six months ago, it decided was the proper amount to pay Dr. Rotherham after a proved successful career, during which he had brought the work to its present admittedly high state of efficiency. Dr. Rotherham's maximum having been £900 with emoluments, the committee proposed a salary for the next holder of the office beginning at £700 per annum, rising by annual increments of £50 to £900, with emoluments of unfurnished house and washing. The committee said it might be admitted at once that the proposed salary would not attract into the service medical superintendents of important county asylums, but from a return of salaries paid at those asylums it was clear that to do this would involve such a very substantial addition to the proposed salary as would not only be in conflict with the decision arrived at in Dr. Rotherham's case, but would in fairness involve an immediate reconsideration of the salaries of all of the medical superintendents in the service. That being so, the field outside the Board's own service from which candidates would be drawn was restricted to a few medical superintendents of smaller asylums and to assistant medical officers, and there was no reason to suppose that, if it were eventually found necessary to advertise, the remuneration would not be sufficient to attract such candidates. As to the steps to be taken to fill the position, the committee wished to consider the claims and qualifications of officers already in the Board's service for the following reasons. It was well known that for some time past there had been the greatest difficulty in securing candidates for vacancies as assistant medical officers in the asylums. This difficulty was certain to be increased if it was once understood by possible candidates that as soon as there was a higher post to fill it was the Board's practice to search outside the service without first even considering the claims of officers who had been in it for some time. If this was to be the practice it was only right that candidates should be warned of it at the outset instead of being left to believe, as they were at present, that when there were higher positions to be disposed of existing officers, if they had served the Board with success over a period of years, would have, at any rate, priority of consideration. This was the general practice of other bodies, and obviously if it was not to be followed by the Board, the Board's officers would only get second consideration both inside their own service and outside, and would have practically no prospects of promotion. In such circumstances the Board could hardly hope to attract the best type of junior officer. In the present case there were practically no institutions comparable with Darenth, and the applicants attracted would be men who would not have had experience of that class of work. The committee mentioned that in the infectious and children's hospitals services no medical superintendent had been taken from outside the service for over 20 years. Only once in the last 20 years had an advertisement been issued in those services for a medical superintendent. If it should appear that no existing officer could be recommended for the vacant position the committee would have no hesitation in advising the issue of advertisements. The Board authorised the Asylums Committee to consider in the first instance the claims and qualifications of officers already in the service for the post of medical superintendent at Darenth.

THE PREVALENCE OF CANCER IN THE UNITED STATES.

THERE are differences of opinion as to whether cancer has increased to any great extent during the past 20 or 30 years in the United States. There are those who hold that such increase is only apparent, attributing the seeming prevalence of malignant disease to the greater skill in diagnosis of the modern practitioner and the far better kept records. Mr. Frederick L. Hoffmann, of the Prudential Insurance Company of America, read before the Clinical Congress of Surgeons of North America at Chicago a paper which may throw light on the matter. Mr. Hoffmann believes that the cancer death-rate in the United States is unquestionably on the increase among both sexes at all ages over 40. He has estimated the number of deaths from cancer in the United States for 1912 at about 71,000, of which 28,041 were deaths from cancer of the stomach and liver, 10,790 were of the female organs of generation, 9371 were of the peritoneum, intestines, and rectum, 6886 were of the breast, 2769 were of the buccal cavity, and 2627 were of the skin, while in addition thereto 10,507 deaths were due to cancer of other organs and parts. He takes the stand that it is absolutely incredible that the large increase in had complications, 5 septic, 5 capillary bronchitis, and 15 bronchopneumonia, with 6 deaths. In all there were 7 deaths in 35 cases, or a mortality of 20 per cent. This compares favourably with the statistics given by Comby—i.e., 69 per cent. in complicated cases. Dr. Galli explains the rationale of this treatment by calling attention to the hypoleucocytosis which occurs in the periods of invasion and eruption. The group of polynuclear neutrophiles is chiefly concerned in this leucopenia, and is reduced to a very small number, almost the whole of the white corpuscles being represented by lymphocytes. It may hence be inferred that the toxin of measles is negatively chemiotactic for the bone marrow, which according to Ehrlich is the focus of production of the polynuclear neutrophiles, and perhaps positively chemiotactic for the spleen and lymphatic glands, which according to Blumreich and Jacoby are the foci of production of lymphocytes. Now, since the polynuclear leucocytes are the defenders of our organism, their marked diminution in the second and third periods of measles is the cause of the diminished resistance, and explains how this special exanthem is more than any other susceptible of aggravation and of complications. In such circumstances electrargol represents the ideal and rational remedy, says an article in the *Gazzetta degli Ospedali e delle Cliniche*, since it stimulates those hæmopoietic organs (bone marrow) which the toxin of measles paralyses, inducing a defensive polynuclear leucocytosis, while it also destroys and renders harmless the toxins which jeopardise life by disturbing the functions of the viscera.

TRANSPLANTATION OF THE TESTICLE.

IT is rather surprising to learn from the paper by Dr. Victor D. Lespinasse in the *Journal of the American Medical Association* for Nov. 22nd that so long ago as 1849 experiments on testicular transplantation were successfully carried out by Berthold, who worked with roosters, transplanting the testicle into the peritoneal cavity. Other investigators have used other animals since, and a short time ago Hammond and Sutton, of Philadelphia, transplanted a whole human testicle into the scrotum of a patient who had but one sound one. In this case the grafted organ "took," but apparently underwent subsequent atrophy; and the functional result cannot, of course, be ascertained, since the recipient of the transplanted testicle already had one sound one. The case reported by Dr. Lespinasse falls within a different category altogether, both in respect of the nature of the operation and the indication for its performance. His patient was a man of 38 who had lost both testicles, one in an accident, the other —which had failed in its normal descent—in a hernia operation. His chief reason for desiring treatment was that he was sexually impotent. Dr. Lespinasse writes that a testicle from a normal man was easily obtained; he was surprised at the number available. The two patients were anæsthetised at the same time; the scrotum of the recipient was opened high up and a "bed" prepared as for the reception of an undescended testis. A second "bed" was made in the depths of the rectus abdominis muscle. The healthy organ was next removed and cut transversely into a series of slices about 1 millimetre thick. The central slice and the one next to it were taken out and set down in the midst of the rectus abdominis, another slice being placed in the scrotal "bed." Recovery was uneventful so far as the healing of the wounds was concerned; sexual desire and capacity for erection returned on the fourth day, and have continued for the past two years. At the discussion which followed Dr. Lespinasse's description of this remarkable case allusion was made to the successes achieved by Tuffier and another in analogous operations on the ovaries, but it seems that there is no other recorded example of such a proceeding in relation to the male.

THE TOXICITY OF BACTERIA.

IT has generally been supposed that pathogenic bacteria produce their evil effects by means of two classes of poisons—one the so-called exotoxins, analogous in some measure to the excretions or secretions of higher organisms, and the other the endotoxins, usually regarded as existing within the bodies of the bacteria and liberated only by their death. The latter on this view are somewhat analogous to the poisonous bodies laid up within the cells of some plants, products of the metabolism of the living cells, but distinct from the actual protoplasm. A novel and interesting hypothesis as to the nature of bacterial toxicity has recently been put forward by Dr. F. H. Thiele and Dr. D. Embleton,[1] based to some extent on Friedberger's work, according to which the toxins of bacteria are in reality cleavage products derived from their living proteid substances under the influence of the ferments present in the body of the host. But it is only at a certain stage in the process of disintegration that the cleavage bodies are toxic. From this it follows that, given the power of existing and multiplying in the body of a living animal, the injurious nature of a bacterium depends on the quantity and consequent vigour of action of the host's ferments. There must be just enough of these to hydrolyse sufficient bacterioprotein to cause toxic effects, but not enough to carry this process so far and so fast as to break up the toxins themselves before they can do harm. A bacterium may therefore be harmless to a particular animal host if, on the one hand, the latter has no ferments capable of digesting it or such a poor supply of these that the process is too slow to produce poisons in sufficient concentration; or, on the other hand, if the ferments are so plentiful and active as to prevent accumulation of toxic cleavage products. Again, a harmless bacterium can be rendered pathogenic if suitable ferments can be produced in the body of the host to effect the needful degree of digestion. In proof of this Dr. Thiele and Dr. Embleton have succeeded in rendering saprophytic organisms, such as bacillus phlei (the grass bacillus), the smegma bacillus, and others lethal for rabbits by sensitising the animals by a preliminary vaccination with the germ. It is interesting to note that the acid-fast organisms just mentioned produce under these conditions typical tubercles and caseation; they acted, in fact, just like tubercle bacilli, thus raising the question of a possible development of the tubercle bacillus from common saprophytic organisms. The most striking feature, however, of the views propounded by Dr. Thiele and Dr. Embleton is the harmony introduced between the phenomena of immunity and those of anaphylaxis, which have hitherto seemed almost contradictory. The anaphylactic state corresponds with the condition of an animal in which the correct amount of ferment is present to render an organism pathogenic, whereas an immune animal has either so much antibody that the cleavage products are destroyed—acquired immunity—or so little that no ill-effects are produced—some forms of natural immunity. For the present the hypothesis sketched above can only be regarded as tentative and awaiting confirmation or refutation, but it is certainly ingenious and worthy of attention.

THE AUTOMATIC REPRODUCTION OF DOCUMENTS.

A GREAT part of the distinct advance that has been made in recent times in all branches of science is undoubtedly due to the preservation of records. Sometimes the data have been consciously selected for their known or expected bearing on some recognised problem. Occasionally they have been noted merely because of a recognition of the fact that the future realisation of a newly recognised factor in some problem may convert mere collections of facts into fertile fields of knowledge. One of the chief obstacles to the systematic collection of facts, whose immediate bearings on some problem are not yet perceived, has hitherto lain in the immense amount of clerical labour involved. The Bureau of Records in the Borough of Manhattan, New York, has recently taken a step in advance in this work by utilising photography wherever possible to perform this hitherto clerical labour.[1] Copies can thus be reproduced of such important records as permits for burial of people who die abroad and other documents containing often much illegible handwriting or curious signatures or impressions of seals. Records in foreign languages, necessitating extreme care in transcription and calling under the old methods for the services of some intelligent person acquainted with the language in question, are reproduced by photography with accuracy and fidelity and with minimum loss of time. The process is, of course, applicable to any documentary evidence, such as certificates of births, marriages, deaths, sickness, and what not. Indeed, it may have entirely unlooked-for extensions as soon as it becomes general. The work is performed in New York by exposing in a holding frame the document to be copied for from 5 to 12 seconds before a suitable camera containing a large roll of specially prepared paper, the required amount being unrolled, exposed, and passed into the developing tank, automatically cut, and thrown into the fixing bath, from which it emerges complete, except for a washing. The result is a positive print, without the intervention of a negative. By this process, it is stated, sheets may be copied at the rate of two a minute, the resulting copy being an exact reproduction free from any possibility of copyist's errors. The utility of such a process calls for no comment.

DISLOCATION OF THE PROXIMAL PHALANX OF THE GREAT TOE.

IN the *Journal of the American Medical Association* of Dec. 6th, 1913, Dr. P. G. Skillern has reported a case of a very rare injury—dislocation of the proximal phalanx of the great toe. A man, aged 56 years, went to hospital with the history of having been kicked by a horse nine weeks previously and of having been treated at another hospital for an injury to the left knee. He complained of pain in the great toe. Examination showed fixation of the toe in extreme extension and crepitation at the metatarso-phalangeal joint. A skiagram revealed displacement of the proximal phalanx of the hallux on to the dorsum of the head of the metatarsal bone. The sesamoid bones were displaced from the plantar aspect to each side of the joint. Under nitrous oxide an attempt at reduction was made with Levy's apparatus, but in consequence of laceration of the skin had to be abandoned. The method proposed by Dr. Crosby, of New Hampshire, in 1826 for reducing dislocations of the thumb, which has been commended by the elder Gross, was then adopted with success. The toe was *raised perpendicularly and strong pressure* was applied against the base of the phalanx, so as to push it from behind forward and from above downward. Reduction was maintained by strapping the hallux down on a plantar splint. Evidently the injury was overlooked at the other hospital. The deformity must have been greatly increased during the intervening nine weeks by contraction of the extensor hallucis proprius. The injury is so rare that Gross stated in his "System of Surgery" that he had seen but two cases. Of 22 cases of luxation of the proximal phalanges of the toes Malgaigne found that 19 were of the great toe. In Holmes's "*System of Surgery*" *the analogy between this dislocation* and that of the corresponding phalanx of the thumb is pointed out as well as the similar difficulty in reduction. In 4 out of 10 cases referred to by Malgaigne reduction could not be accomplished. In accounting for this difficulty the statement of Gross is not borne out by the present case. He said: "It depends probably on the manner in which the adductor muscle and the sesamoid bones are dragged by the displaced phalanx backward over the extremity of the metatarsal." Here the skiagrams showed clearly the position of the sesamoid bones and that they in no way interfered with reduction.

AT the meeting of the Section of Medicine of the Royal Society of Medicine, to be held on Tuesday, Jan. 27th, there will be a discussion on Vaccines from the Standpoint of the Physician. Dr. T. J. Horder will open the discussion, and will be followed by Sir John McFadyean and Dr. Charlton Briscoe. The discussion will probably be continued on the following Tuesday, Feb. 3rd. Members wishing to take part in the debate should communicate with Dr. John Fawcett, the honorary secretary of the section, at the society's house, 1, Wimpole-street, London, W.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON).—The course of lectures on the Neuroses and Psychoses of Children, which was being delivered by Dr. Francis Warner, consulting physician to the London Hospital, during the winter session of 1913, will be continued during January, February, and March, 1914. These lectures will be delivered every Monday at 4.15 P.M. in the clinical theatre of the hospital, and are intended for students as well as for post-graduates. The subjects remaining to be dealt with are the Study of Modes of Brain Action, Mental Aptitudes, Faults, and Status of the Child; Brain Action corresponding to Motor Signs; Types of Childhood, and Elements of Brain Training; Systematic Training and Mental Hygiene. Further information can be obtained from the Professor William Wright, dean of the college.

TOILET SOAPS FROM AN ECONOMIC AND HYGIENIC POINT OF VIEW.

Introductory.

THE following article contains certain instructive details, brought out in a number of analyses that we have made, in regard to the nature and quality of the numerous toilet soaps now at the disposal of the public. We have decided to treat the question on general grounds, avoiding for that reason any invidious reference to the particular goods of a particular maker. It is obvious that the soap-maker knows more of the details of soap-making than we do, but we may be allowed to approach the subject from the point of view of the consumer, and, therefore, to deal with soap as it reaches the public, devoting special attention to economic and hygienic considerations. Soap-makers doubtless work to their own idea of standards and price, but it is well that they should hear an independent expression of opinion upon these points.

General Considerations.

The cleansing power of soap is universally appreciated. It has been used as a detergent from the earliest ages. To-day its manufacture has reached a pitch of refinement upon which both consumer and maker may be congratulated. The quality of soap is of considerable importance, having regard to the frequency of its use in domestic economy, for it is employed with a regularity and orthodoxy comparable with the ritual of meal-time. Soap and food, in fact, rival one another as matters of resource in the *régime* of the domestic day. Soap occupies this position owing to its property of removing greasy materials which amongst other things are responsible for soiling the skin or clothing. Its essential chemical quality is, in fact, its solvent effect upon fatty substances. If dirt were not invariably accompanied by grease soap would not be required to the extent it is, for greaseless dirt would for the most part be detached by the application of water and mechanical movement alone. A prompt method of removing grease would be by the application of an alkali, but this is inadmissible since alkali has an irritating, because solvent, action upon the skin. The grease-dissolving effect of an alkali, however, can be obtained by introducing it in the form of a comparatively unstable compound of fat and alkali, and this is what soap amounts to. Soap on hydrolysis or solution in water dissociates into free alkali and an acid soap. The acid soap gives rise to a lather with water and the alkali is available for extracting fatty matters.

There is thus obtained both a saponifying and emulsifying action on the substance to which soiling is due. The use of soaps in preference to free alkali is justified by the fact that soap prevents the presence of an excessive proportion of free alkali. The proportion of alkali liberated from soap is small with a small quantity of water, and large with a large quantity. The addition of a large quantity of water does not, therefore, greatly affect the concentration (the amount of free alkali in a given volume of water), since, although much water produces much free alkali, it simultaneously dilutes it. In a word, the advantage of soap for cleansing purposes is that by its use there is an automatic regulation of the proportion of free alkali, which is kept constantly small, and hence the wash water is free from injurious properties. This is the secret of soap's power to remove fatty matters which otherwise are hard to detach. Grease is the anchor of dirt, and soap weighs the anchor. Soap is nowhere provided by nature; it is man's creation, and is, in fact, a chemical. The fatty acid is combined in a definite relation with the alkali, although different fats have different combining values, just as different inorganic acids have different combining values in their union with metals. Soap is thus a salt, and the business of the soap-maker is to effect a satisfactory combination of fatty acid and alkali. The soap produced should possess qualities in accordance with the special purpose for which it is intended to be applied. In the present inquiry we deal, however, only with those soaps which are sold for toilet use, and it is obvious that soap of the highest purity and quality is demanded in this case.

According to an examination of a score or so of toilet or fancy soaps recently purchased upon the open market, it would appear that, generally speaking, the makers contrive to furnish a product of good standard quality. On the whole, the toilet soaps supplied show also a close approximation to a standard of composition. That is to say, the proportion of actual soap present is fairly constant, and the amounts and relations of fat and alkali are much the same in the majority of the samples examined. There are exceptions with which we shall presently deal.

The Prices of Toilet Soaps.

There is, however, as will be seen from the table accompanying, a very wide range in regard to the prices at which toilet soaps are sold. In column 1 of this table the prices of the toilet soaps which were procured for examination are given. In the absence of foreign ingredients the figures shown represent the cost of actual dry soap present in the tablet or bar, and are strictly comparative. They represent, in fact, the actual price paid for the cleansing agent. Soap's essential function is, of course, to cleanse, and in reality it is purchased solely for this property, and yet the prices paid for soap to obtain this advantage vary as much as from 6¼*d.* to 8*s.* 4*d.* per lb. The explanation of this remarkable difference in the price of a substance which serves one and the same purpose is that there are equally wide differences in quality, depending upon the choice of materials in the manufacture. Special fats may, for example, be selected, or a fancy constituent added in the shape of scent, glycerine, or oatmeal. It is difficult to concede that these considerations can advance the price of the material basis to the large extent shown.

The transparent soap, for example No. 18 in the table, which is free from sugar and glycerine and probably, therefore, made with the aid of alcohol, but unscented, is sold at nearly half the price of No. 24, which is also a transparent soap showing a similar composition but with the difference that it is scented. The analyses of these soaps do not indicate any important difference of quality, but the price of the former is 1*s.* 6*d.* per lb. and of the latter 2*s.* 11½*d.* per lb. This suggests that the price of the soap is much higher merely because it contains scent, the proportion of which is very small. Scent seems to be the chief ingredient relied upon to enhance enormously the cost of soap, for it will be noticed that as a rule the scented soaps are the most costly.

Thus, for an eau-de-Cologne soap 1*s.* 9¼*d.* is charged per lb., for an "otto of roses" soap the price is 6*s.* 6*d.* per lb., for a ladies' face soap, also scented, 8*s.* 4*d.* per lb., whereas perfectly good soaps for ordinary toilet purposes can be obtained at 1*s.* per lb. or under. Viewed as mere cleansing agents these costly soaps are nothing like worth the money charged for them, neither do they exhibit qualities which render them particularly more suitable for personal use as cleansing agents than the well-made soaps costing a shilling or less per pound. There is a further point in regard to scent. It is maintained by some authorities that certain essential oils (the bases of scent) are not suitable for tender skins, as these oils are known to produce a skin-reddening action. Amongst essential oils the irritating effects of mustard oil, turpentine, and thymol are well known.

Water in Soap.

The proportion of moisture in toilet soaps shows considerable variation, as will be seen from column 2 in the table. As a rule, moisture is excessive, as might be expected, in the cheaper kinds of toilet soap. The highest amount found was in a cheap soap, a transparent bar—viz., 23·60 per cent., and the lowest 3·60 per cent. in an expensive soap. The majority of the soaps examined showed a percentage of water of from 4 to 8. It is of interest to note that soaps containing an excessive amount of water sometimes contained glycerine or sugar or both. (Examples occur in Nos. 2 and 17.)

The Quantity of Fixed Alkali in Soap.

The amount of fixed alkali in toilet soap is a fairly constant quantity, as will be seen from column 6, which gives the alkalinity of the ash calculated as sodium oxide in the dry soap. Any startling variations in these figures would disclose the presence of inert mineral substances. In the absence of such additions the figures in columns 4 and 5 should show a fair agreement. When pure soap is incinerated it leaves an ash which should be pure carbonate of soda. If the weight of the ash agrees with the amount of alkali found in it and calculated as carbonate of soda, it is evident that the soap must be free from foreign mineral additions. The results show, on the whole, that toilet soaps are free from extraneous mineral matters. Exceptions occur in soaps Nos. 9, 13, 16, and 25, but the amounts are not high. They serve to show, however, that the practice of adding mineral matter to soap which is not essential for its formation is not obsolete, even in the matter of toilet soaps.

Sugar and Glycerine in Soap.

Sugar must be regarded as a foreign constituent of soap. Glycerine does not come quite within this category, since it is a product of the saponification of fats, though, as a rule, it is recovered in soapmaking as a separate substance destined for an entirely different purpose from soap itself. Glycerine is generally a declared constituent of soap when it is present in important quantity. It is commonly found in transparent or semi-transparent soaps, its presence contributing transparency.

Soaps Nos. 3 and 17 in the table are both called glycerine soaps, and the amounts of glycerine recorded are respectively 5·04 per cent. and 19·30 per cent. In addition to glycerine, both soaps contained sugar, the former 2·26 per cent. and the latter 5·76 per cent., which is probably used to aid the glycerine in producing transparency. The glycerine produced in soapmaking tends to produce a translucent soap, especially if castor oil is used as the fatty substance, but a greater degree of transparency is obtained by the addition of extra glycerine. To the presence of glycerine in soap there can be no objection, as apparently glycerine is not offensive to a sensitive skin. One drawback to its use, however, is that it is very hygroscopic, so that it is apt to make the soap "sweat" or get wet on its surface. Sugar replaces glycerine for the purpose of producing a transparent soap, with the advantage that it does not "sweat," but unfortunately sugar has a decidedly irritating action upon sensitive skins, and the sugar soaps should be avoided by those who possess easily irritated skins. The use of sugar in toilet soaps is, however, not very general according to the results of our inquiries. Neither sugar nor glycerine, it should be pointed out, is essential to the production of transparent soaps. They, and especially sugar, represent cheap methods of obtaining that end. By using alcohol to dissolve the product of saponification, undoubtedly a very pure soap is prepared, a soap which more nearly approaches than anything else to the composition of a theoretically pure soap. Whether the theoretical soap is best for all purposes under all conditions of usage is a question which may well be considered. We are content to point out that transparent soaps of excellent quality are prepared which contain neither glycerine nor sugar, but which are prepared by an alcohol process, the only disadvantage of which is to add to cost of production, and therefore to its price to the consumer. For toilet purposes we are inclined to think that the unscented transparent soap prepared by the alcohol process is one of the best soaps adapted for personal use, including the case of a sensitive skin.

Soap and Water.

However pure a toilet soap may be it must always be remembered that in contact with water it hydrolyses and furnishes a solution containing free alkali as explained in the introductory portions of this article. The skins, therefore, that are sensitive to weak alkaline solutions will be sensitive to the purest soap solutions. But they will be spared the effect of an excess of alkali when a well-made soap is used. It is probable that all skins are more or less susceptible to the action of alkali, and this is the chief reason why a well-balanced soap for toilet purposes is desirable. The proportion of alkali set free on dissolution in water varies with different soaps, but not to a very large extent. In column 7 in the table will be found a series of figures giving the percentage of total alkali liberated on hydrolysis in water as in ordinary washing at 110° F. (comfortably hot) for 15 minutes with various soaps. The highest obtained (No. 20) was 41·80 per cent., and the lowest (No. 17) 15·80 per cent., but most of the soaps gave a number approximating to from 33 to 40 per cent.

It is interesting to observe that the glycerine and sugared soaps in each case yielded a relatively small amount of free alkali on hydrolysis. Apparently glycerine or sugar interferes with the rate of dissolution of soap in water. In some cases this may be an advantage, but in others a disadvantage. The soap which hydrolyses freely is likely to be a ready cleanser, but, on the other hand, the soap that hydrolyses tardily may suit the requirements of a delicate skin. According to this a glycerine soap, for example, may prove to be very suitable for the person with a susceptible skin, but such a soap is not calculated to produce the ready and effective cleansing which a soap free from glycerine or sugar would do.

The Fats in Soap.

Pure neutral fats, whatever their origin, can hardly be held accountable by themselves for any prejudicial action upon the skin, but inasmuch as different fats require varying amounts of alkali in order to convert them into neutral soaps the question of what fat is present in soap is of some importance. Cocoa-nut oil or palm-nut oil, for example, requires much more alkali for saponification than does olive oil, tallow, castor or rape oil, and so a soap made with cocoa-nut oil or palm-nut oil would yield more alkali on hydrolysis in water than a soap made with olive oil, tallow, castor, or rape oil.

For the most part modern toilet soaps are made with nut oils, palm-nut oil, and cocoa-nut oil, whereas early in the history of soap-making tallow and olive oil were employed. Modern soaps therefore yield more alkali on hydrolysis than the old soaps. By some authorities this is regarded as a retrograde step. The modern soap-maker tells us, on the other hand, that cocoa-nut or palm-kernel oils are not used merely for cheapness, or for producing a firm soap, but because of their wonderful efficacy as soap-making material, and besides they are sweet and entirely of vegetable origin and do not easily become rancid. The soaps produced with these oils prove also to be rapid and economical washers. A glance down column 12 of the table will show that the neutralisation values of the fatty acids liberated from the toilet soaps which we procured show certain variations. The lowest figure is 187 and the highest 223. These figures indicate the quantity of potash (KOH) required to neutralise 1000 parts of fatty acid. The majority of the soaps gave numbers well over 200, which points to the use of palm-kernel oils or cocoa-nut oil or a mixture. Some of the soaps, however, gave figures well below 200, and these included some relatively expensive soaps.

There is a great difference in the prices of oils used in soap-making, which must govern to some extent the price of the finished material, and we are told that the recent all-round advance in the price of soap is attributable to the increasing demand for cocoa-nut and palm-kernel oils for edible purposes, and as a matter of fact for the manufacture of butter substitutes. Further observations are presented in the table in regard to other physical constants given by the fatty acids obtained from toilet soaps. The melting points and solidifying points, for example, were observed, and a figure is given, called the Valenta figure, which records the temperature at which a mixture of equal volumes of acetic acid and fatty acid results in a uniformly clear and bright solution. It will be seen that the melting and solidifying points (see Columns 10 and 11) do not show any sharp distinction when comparing cheap and expensive soaps, but the majority of the figures given are well above that of olive oil, which is 26. Nor do the Valenta figures (see Column 13) help materially to differentiate the cheap from the expensive soaps, but it may be remarked that the majority of them approach the figures given by palm and coconut oils. Altogether the physical constants tend to show the use of the same fats throughout the series, which includes both cheap and expensive soaps. It should be pointed out, however, that no safe interpretation can be placed upon these results since the soap maker invariably uses a mixture of fats.

Free Alkali in Toilet Soaps.

Column 14 records the presence or absence of free alkali in toilet soaps. It will be seen that in four cases which include soaps costing under a shilling per pound there was free alkali present, and in two cases of soaps costing over that amount there was evidence also of free alkali. When sugar was present in the soap free alkali was found in two cases out of three. The presence of free alkali in toilet soap is undesirable, but, on the whole, the manufacture of soap is now conducted on such scientific and carefully regulated lines that the output of quite neutral toilet soaps is practically the rule, according to our observations. There are superfatted soaps on the market, but except perhaps that they are generally made with extra care they possess no advantage, at least the suggestion that a small excess of fat gives the soap emollient properties is not accepted by all authorities. It is safe to say, at all events, that a slight excess of fat is to be preferred to the presence of free alkali.

Fancy Names.

The use of fancy names, such as buttermilk, cream, cucumber, honey, and others, where none of these things is present in a soap, is open to criticism. There can be little doubt that a section of the public is guided in the purchase of a soap by its name, the impression being that the name has a definite meaning, implying some superior quality of soap or the presence of a soothing material. Such terms as buttermilk, honey, cream, and cucumber are applied to soaps which are just as plain in their composition as brown windsor. They appear at any rate to be innocent of the presence of the various materials hinted at, and so the description has no literal foundation.

Conclusions.

To summarize, the results show that the toilet soaps on the market as a whole evidence a degree of purity and adaptability for toilet purposes which redound to the credit of the soap maker. It is obvious that modern soap making is, generally speaking, founded on scientific lines and run on a system of control which turns out a standard product equal to ascertained requirements. Gross adulteration in regard to toilet soaps does not appear to exist. The only foreign ingredient we found present in important quantity, and to which exception may be taken on account of its irritant properties, is sugar. The presence of free alkali in toilet soap is a comparatively rare occurrence, but it would appear that in some instances the degree of purity attained in toilet soaps induces makers to demand a very extravagant price, and apparently high grade scents are resorted to as a kind of justification for this demand. It is doubtful whether toilet soap is rendered more acceptable to the skin by the scenting process. Essentially, soap is required for cleansing purposes, and so long as toilet soaps fulfil this rôle without doing harm to the skin they perform all that is necessary. We found this function discharged by toilet soaps sold at moderate prices. Even the purest soaps may give rise to irritation on certain delicately constituted skins. And it must be remembered that in any case the use of soap connotes the use of a weak but regulated quantity of alkali, and so its excessive employment should be avoided, when the work of cleansing has been done it is well to remove any excess of soap with all reasonable speed.

MEDICINE AND THE LAW.

Eastes v. Russ.

A FULL account of the issues in this action tried by Mr. Justice Sargant will be found in THE LANCET of June 7th, 1913, p. 1618. The plaintiff having appealed, the Court of Appeal recently affirmed in effect the judgment delivered in the court below, although differing from the reasoning by which Mr. Justice Sargant arrived at his conclusions. His lordship, it will be found, held that a restrictive condition preventing the defendant from engaging in laboratory work within ten miles from the place where he was employed by the plaintiff was co-extensive only with the period of his employment, and also that it was ambiguously expressed. He was not prepared to find that the condition, if for life, was in restraint of trade and more far-reaching than was necessary to protect the plaintiff. In the Court of Appeal the Master of the Rolls and Lord Justice Phillimore dissented from the interpretation of the condition as being co-extensive with the term of employment, but held that the restraint sought to be imposed went beyond what was reasonably necessary for the plaintiff's protection, and that accordingly the appeal must fail. Lord Justice Swinfen Eady dissented, being of opinion that the appeal should be allowed.

Bolliger v. Bridger.

After a long trial before Mr. Justice Lawrence and a special jury, a verdict for the defendant was returned in an action for assault brought by a girl, 18 years of age, named Freeda Bolliger, who sued through her father as her next friend. The plaintiff had consulted the defendant, Mr. J. D. Bridger, on three occasions in August last, and she alleged that his conduct to her was not that which the treatment of her case required, and that it constituted an assault. In consequence of her daughter's statements the girl's mother attacked Mr. Bridger with a dog whip, and the summons which he took out against her was dismissed. This was followed by a letter from the plaintiff's solicitors to the defendant asking him to pay compensation, which he declined to do, intimating that he should welcome inquiry into the whole of the facts of the case. After the evidence for both parties had been fully gone into, his lordship, in summing up, told the jury that anyone going to a medical man for treatment gave an implied assent to anything reasonably necessary for that treatment. The evidence showed that there had been either a diabolical act by the defendant or a fantastic dream on the part of the girl. There was no evidence to show that she was hysterical but, on the other hand, there was a medical man working very hard for a meagre remuneration, as to whose high character his friends, teachers who had instructed him, and eminent members of his profession to whom he had been an assistant, were agreed. It was a matter of human experience that women occasionally made unfounded charges against men, and a commonplace of medical prudence to secure, if possible, the presence of a third person in treating them for the protection not of the patient but of the medical attendant. It was, he suggested, a question not of lying on the part of women but of hallucination and of a perverted conception of what had happened to them. The jury found a verdict for Mr. Bridger. It is a commonplace of forensic practice that charges such as that levelled against him are among the easiest of accusations to bring and the hardest to repel, and that the nature of their professional duties renders medical practitioners peculiarly, and apparently unavoidably, liable to them. Mr. Bridger is to be congratulated warmly upon the satisfactory conclusion of an incident in his professional career of a very painful character.

REPORT ON SANITARY MEASURES IN INDIA IN 1911-12.[1]

European army.—It is very satisfactory to be able to note that the improvement in the health of the European troops serving in India, which has progressed steadily during the past few years, has been maintained. The average daily strength of the European army, including officers, during the year under review was 72,371. The chief causes of mortality were hepatic abscess, enteric fever, heat-stroke, and cholera. It is worthy of note that for the first time on record the death-rate from enteric fever is lower than that of hepatic abscess. Only 24 deaths were recorded from enteric as compared with 46 in 1910 and 113 in 1909. From all causes 515 men were invalided, as compared with 563 in 1910 and 649 in 1909. Diseases of the ear were the chief cause of loss in 1911, the number so invalided being 62. Tubercle of the lungs took second place, 55 being invalided, as compared with 71 the previous year. Nervous diseases caused 54 invalidings and mental diseases 40. As regards the prevalence of important diseases in plain stations where the average annual strength was 500 or more, the incidence of enteric fever was greatest at the cantonments of Bareilly, Lucknow, Belgaum, Fyzabad, and Nowshera; of malaria at Bellary, Mhow, Muttra, Peshawar, and Jubbulpore; of dysentery at Poona, Bangalore, Fyzabad, Fort William, and Lucknow; and of venereal diseases at Colaba, Bellary, Bangalore, Fyzabad, and Madras, including St. Thomas's Mount Cholera caused 38 admissions and 21 deaths; of these, 26 cases with 12 deaths occurred amongst the 1st Royal Scots at Benares, the source of infection being traced to the butter-supply from an infected dairy in the city where the disease was prevalent. The epidemic was confined to British troops and subsided in three days when precautions had been taken to prevent further infection. Seven cases with 4 deaths occurred amongst the 4th King's Royal Rifles when marching through Dehra Dun from Chakrata. Only 1 case of small-pox occurred during the year. The admissions to hospital for malaria numbered 6527, as compared with 9572 in 1910. There were 6 deaths and 7 invalidings to England. The number of cases of cases of enteric fever is the lowest on record. Throughout the whole of India only 170 cases are returned with 22 deaths; of these, 106 were amongst uninoculated men and 64 amongst the non-inoculated, but as the inoculated amounted to 85 per cent. of the whole the number of the inoculated exposed to infection is more than five times greater than the number of non-inoculated men. Excellent work has been carried out at the enteric fever convalescent depôts at Naini Tal and Wellington, many carrier cases being detected and segregated. Treatment of carriers by means of an autogenous bacillary emulsion has been definitely found to be inoperative.

Indian army.—The health of the Indian troops throughout the year has been very good. Including those on duty in China and in other stations outside India the average strength was 131,213 as compared with 131,274 in the previous year. It is satisfactory to note that the admission, constantly sick, death, and invaliding rates were lower than in 1910. The chief causes of sickness were malaria, pyrexia of uncertain origin, respiratory diseases, and dysentery; the chief causes of death were pneumonia, enteric fever, malaria, and respiratory diseases. The number of invalidings was 581 as compared with 684 in 1910, the chief causes of this source of loss being tubercle of the lungs, injuries, anæmia, and debility and venereal diseases. The highest death-rate in any of the larger stations was 14·18 per 1000 at Dehra Dun, the chief cause of mortality being enteric fever. The number of cases of cholera in the Indian army was 16 and the number of deaths was 14. No individual regiment had more than two cases. Small-pox caused 36 admissions with no death. Malaria gave 13,778 admissions and 55 deaths. Enteric fever caused 302 admissions with 55 deaths. Anti-typhoid inoculation is being introduced in many regiments. There was a marked increase in the incidence of plague. The total number of admissions during the year was 95 with 35 deaths, as compared with 31 cases with 22 deaths in 1910. Tubercle of the lung gave 56 admissions amongst Gurkhas with 11 deaths. Dysentery caused 2971 admissions with 16 deaths, and venereal diseases 1950 admissions with 4 deaths.

General population.—This section of the report deals with the several provinces of British India. The total number of births and deaths registered were 9,209,703 and 7,639,544 respectively. The deaths from the chief diseases were as follows: Cholera, 354,005; small-pox, 58,535; plague, 733,582; fever, 4,207,356; dysentery and diarrhœa, 253,636; respiratory diseases, 223,822; and "all other causes," 1,710,641. Taking British India as a whole, the number of deaths under each of the headings tabulated, except under small-pox and plague, were fewer in 1911 than in the preceding year. All the provinces except Bengal, Eastern Bengal and Assam, and the Central Provinces, contributed towards the increase under small-pox. The increase in the number of deaths from plague was caused principally by epidemics in Bengal, the United Provinces of Agra and Oudh, the Punjab, and Bombay. The cholera mortality of India was reduced from that of 1910 by nearly 18 per cent., and the number of deaths from "fever" shows a decline when compared with the preceding two years. As regards the Red Sea pilgrim traffic, it is noted that 18,014 pilgrims left the Port of Bombay for Mecca *viâ* Jeddah; 8278 of these were vaccinated before they left Bombay and many of the remainder had been vaccinated before they left their homes. No case of either plague or small-pox occurred on the 23 ships carrying them, but on the outward voyage 106 deaths occurred among the pilgrims, the cases being attributed to fever, old age, debility, &c.

The jails of India.—The mean daily number of prisoners in India, Burma, and the Andamans during 1911 was 109,099—1356 less than in 1909. The rates of mortality from all causes fell to 19·09 per 1000 from 21·62 in 1910. The diseases to which the greatest amount of sickness were due were: malaria (admission rate 113 8 per 1000), dysentery (56·6), diarrhœa (38·6), and respiratory diseases (28·3); while the principal causes of death were tubercle of lungs (3·65), dysentery (2 91), and pneumonia (2·37). Excluding tubercle of the lungs there has been a tendency towards lower death-rates from all other causes as compared with 1910. An epidemic of scurvy and pyorrhœa alveolaris occurred at Sylhet, which was responsible for 35 deaths as compared with 18 in the previous year.

Vaccination.—During the year 1911–1912 there were performed in British India a total of 9,684,249 vaccination operations, there being an increase in every province except Coorg, the average cost of each successful case being approximately threepence. In the Assam report it is explained that the failure of the lymph was due to one or both of two causes—first, a decrease in the potency of the lymph strain; and second, to exposure to heat during the interval between issue and use. To remedy the first, endeavour was made to exalt the potency of the lymph by passage of the strain through a rabbit before being re-inoculated on calves. As to the second, the lymph was packed in flasks made on the "Thermos" principle and sent to the provincial laboratory at Dacca, where it was packed in ice and sent out to vaccinators by post in weekly supplies. The result of the experiment showed that if suitable measures are employed to ensure the potency of the lymph by careful selection of vesicles and passage through an alternative vaccinifer no special arrangements of packing, despatch, and distribution are necessary to prevent October and November failures. In the United Provinces of Agra and Oudh it is reported that there was a decrease in the issue of lymph in glass capillary tubes and an increase of the supply in bulk. This was due to the introduction of the method of supplying lymph in metal collapsible tubes which are cheaper and reduce labour. Arm-to-arm vaccination has now been replaced by vaccination with calf lymph in 22 districts, and during the ensuing season it is proposed to extend the supply to 11 additional districts, bringing the total to 33 of the 48 districts of the United Provinces. In the North-west Frontier Province the attitude of the people towards vaccination is not one of hostility, but there is the usual amount of apathy, laziness, and of disinclination to be annoyed. The principle involved and protection conferred are well understood, and it is always noted that if small-pox is looming on the horizon the vaccination returns go up considerably. It is considered inadvisable to attempt to enforce the Vaccination Act in the province; the steady increase in the work is regarded as proof that the people are beginning to appreciate the benefits of the proceeding.

[1] East India (Sanitary Measures), vol. xlv., presented to both Houses of Parliament by Command of His Majesty, 1913. London: Wyman and Sons. Price 11*d.*

Medical institutions.—This section of the report is contributed by the Director-General of the Indian Medical Service. The State-public, local fund, and private-aided hospitals and dispensaries in British India now number 2707, an increase by 37 on the figure for 1910, and the demand for more is felt everywhere. The system of supplying treatment to the population in areas where no dispensaries yet exist, by means of an itinerating staff, has been extended in the United Provinces of Agra and Oudh and in the Punjab, and has been attended with much success. Expenditure rose from £783,123 in 1910 to £863,168 in 1911—an increase of 10 per cent.; but Indian subscriptions remained practically stationary, amounting to only £47,252, or a little over 5 per cent. of the whole. The population generally shows little desire to share in the burden of providing the institutions, though it makes use of them in ever-increasing numbers. During the year under review the total number of in-patients treated were 460,671 and out-patients 27,595,176, while the total number of operations performed was 1,139,060. In Calcutta it is noted that the new (Rogers) treatment for cholera was most successful, the recoveries varying from 60·77 per cent. to 70·59 per cent. In the United Provinces of Agra and Oudh the institution of travelling dispensaries has been very successful, and more than accounted for the decrease in attendance elsewhere, as they dealt with over 300,000 patients not included in the official totals.

Medical colleges and schools.—There are four colleges which afford the course for university degrees and also train military assistant surgeons. During the year the students numbered 1553 civil and private male, 93 female, and 204 military students. There are 14 schools which train civil, military, and private pupils for the passing-out diploma. The students numbered 1865 male, civil and private, 287 military, and 135 females. The X ray institute at Debra Dun continues to carry out excellent work. Two classes of instruction were held during the year. The number of post- [illegible] these included officers [illegible] ssistant surgeons, and [illegible] of new apparatus employed in electro-therapy has been received by the institute during the year, including apparatus employed in ionic medication. No case of X ray traumatism occurred to any of the staff, students, or patients of the institute.

Sanitary works.—In the past, owing generally to funds being limited, progress in respect of sanitary works has necessarily been slow. Interest in sanitation has, however, been growing, and a distinct advance has now been possible in consequence of the large and special grants made to the provinces by the Government of India. In Bengal a steady improvement is recorded in the working of the septic tank installations. A new type of distributor has been designed which has largely solved the question of distribution over the filter beds. It is claimed that the septic tank latrine installations are now practically perfect in design. The chlorinating of all the effluent is now stated to be extremely we[illegible] and it is seldom that a mild effluent is found that is practically sterile. In the United Provinces of Agra and Oudh good progress has been made in drainage works and other forms of town improvement in the larger municipalities. The waterworks, with the exception of those at Allahabad, generally gave good results. In the Punjab, it is noted that sewerage on a large scale has commenced and that the waterworks extension is in progress. In the Central Provinces a considerable degree of improvement is reported in municipal towns, but it is said much remains to be done. Although poor, as most of the municipalities are, the provincial Sanitary Commissioner remarks that this is not the cause of sanitation being gravely defective—it is because responsible persons do not personally interest themselves and municipal members have not sufficient responsibility.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEETING OF COMITIA.

AN extraordinary Comitia was held on Dec. 22nd, 1913, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The following communications were received: 1 From the secretary of the Royal College of Surgeons of England, dated respectively Nov. 13th and Dec. 15th, reporting proceedings of the Council of that College upon those days. 2. From the secretary of the Royal Sanitary Institute, dated Nov. 25th, inviting the College to appoint delegates to their Congress which is to be held in Blackpool in July next. It was resolved that it should be left to the President to appoint delegates at a later date. 3. From the chairman of the Royal Commission on Venereal [illegible] was delegated to nominate Fellows as witnesses. 4. From Mr. A. M. Burke, dated Dec. 6th, asking permission to photograph the portrait of Sir Thomas Millington. The request was granted.

A report was received from the Representative of the College upon the General Medical Council (Dr. Norman Moore).

A report was received, and adopted, from the Committee of Management dated Dec. 16th. The report was as follows:—

1. [illegible] of th[illegible] Tropi[illegible] comm[illegible] propo[illegible] stitut[illegible]

I[illegible]

I[illegible] and (*c*) practical laboratory work in the following subjects: [illegible] parasitology, [illegible]

P[illegible] [illegible]ral questions; [illegible] l diseases and hygiene. This will include helminthology, protozoology, zoology, and entomology in their relations to clinical medicine.

III. The fee for admission to Part I. is £5 5*s*., and the fee for admission to Part II. is £4 4*s*.

IV. Candidates may enter for Parts I. and II. separately, or together, but they will not be allowed to proceed to Part II. until they have passed Part I.

2. The committee also recommend that the following institutions which have been visited by a member of the committee and reported on as fulfilling the requirements of the Board, be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry and physics—viz.: St. Chad's College, Denstone; Bournemouth Municipal College; and Bournemouth School.

After some further formal business the PRESIDENT dissolved the Comitia.

PRESENTATION TO A MEDICAL MAN.—Dr. Emyr Owen Price, medical officer and public vaccinator for Bangor district of Carnarvonshire, has been presented by his professional colleagues with a motor-car in recognition of the work which he has done on behalf of his profession in connexion with the National Insurance Act.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, and whose aggregate population at the middle of 1913 is estimated at 17,852,766 persons, 8321 births and 4997 deaths were registered during the week ended Saturday, Dec. 20th, 1913. The annual rate of mortality in these towns, which had been 14·1, 13·2, and 14·5 per 1000 in the three preceding weeks, further rose to 14·6 per 1000 in the week under notice. In the first 12 weeks of the December quarter the mean annual death-rate in these towns averaged 13·8, or 0·1 per 1000 more than the corresponding rate in London. Among the several towns the death-rate in the week under review ranged from 4·2 in Ilford, 6·7 in Acton, 7·6 in Gillingham, 7·9 in Bury, and 8·2 in Cambridge, to 23·2 in Dewsbury, 23·6 in South Shields, 24·5 in Smethwick, 26·4 in West Bromwich, and 29·0 in Middlesbrough.

The 4997 deaths from all causes were 45 in excess of the number in the previous week, and included 341 which were referred to the principal epidemic diseases, against 269 and 324 in the two preceding weeks. Of these 341 deaths, 96 resulted from infantile diarrhœal diseases, 69 from diphtheria, 62 from measles, 56 from whooping-cough, 38 from scarlet fever, and 20 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·0, against 0·8 and 0·9 per 1000 in the two preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 152, 101, and 94 in the three preceding weeks, were 96 in the week under notice; of this number 27 were registered in London, 7 in Manchester, 5 in Stoke-on-Trent, and 4 each in Birmingham, Sheffield, and Rhondda. The deaths referred to diphtheria were 69, against 65, 45, and 70 in the three preceding weeks, and included 12 in London, 4 in Stoke-on-Trent, 4 in Manchester, and 3 each in Southampton, Birmingham, and Liverpool. The fatal cases of measles, which had been 39, 40, and 54 in the three preceding weeks, further rose to 62, of which number 12 occurred in Burnley, 8 in Middlesbrough, 7 in Sheffield, 5 in London, 4 in West Bromwich, and 3 each in Stoke-on-Trent, Stockport, and Bradford. The deaths attributed to whooping-cough, which had been 39, 32, and 57 in the three preceding weeks, were 56, and included 10 in London, 6 in Birmingham, 6 in Liverpool, and 3 each in Norwich, Manchester, Hull, and Leeds. The deaths referred to scarlet fever, which had been 35, 37, and 23 in the three preceding weeks, rose to 38; 7 deaths from this disease were recorded in London, 5 in South Shields, 3 in Birmingham, and 2 each in Great Yarmouth, Wallasey, Liverpool, and Sunderland. The fatal cases of enteric fever, which had been 18, 14, and 26 in the three preceding weeks, declined to 20, and included 5 in London and 2 in Newcastle-on-Tyne.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 4112, 4143, and 4137 at the end of the three preceding weeks, had further declined to 4048 on Dec. 20th; 458 new cases were admitted during the week, against 618, 524, and 552 in the three preceding weeks. These hospitals also contained on Dec. 20th 1156 cases of diphtheria, 169 of whooping-cough, 60 of measles, and 58 of enteric fever, but not one of small-pox. The 1278 deaths from all causes in London were 48 in excess of the number in the previous week, and were equal to an annual death-rate of 14·7 per 1000. The deaths referred to diseases of the respiratory system, which had been 261, 227, and 291 in the three preceding weeks, further rose to 307, and were 22 in excess of the number in the corresponding week of last year.

Of the 4997 deaths from all causes in the 96 towns, 197 resulted from various forms of violence, and 431 were the subject of coroners' inquests. The causes of 25, or 0·5 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Liverpool, Manchester, Leeds, Bristol, Bradford, Hull, and in 59 other smaller towns. Of the 25 uncertified causes of death, 6 were registered in Birmingham, and 2 each in Preston, Sheffield, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,259,600 persons at the middle of 1913, 1249 births and 751 deaths were registered during the week ended Saturday, Dec. 20th, 1913. The annual rate of mortality in these towns, which had been 17·0, 15·6, and 17·0 per 1000 in the three preceding weeks, further rose to 17·3 per 1000 in the week under notice. During the first twelve weeks of the December quarter the mean annual death-rate in these towns averaged 15·4, against a corresponding rate of 13·8 per 1000 in the 96 large English towns. Among the several Scotch towns the death-rate in the week under review ranged from 8·9 in Perth, 9·8 in Clydebank, and 13·5 in Hamilton, to 22·5 in Paisley, 25·6 in Kilmarnock, and 26·0 in Ayr.

The 751 deaths from all causes were 17 in excess of the number in the previous week, and included 79 which were referred to the principal epidemic diseases, against numbers rising from 68 to 86 in the four preceding weeks. Of these 79 deaths, 39 resulted from measles, 14 from infantile diarrhœal diseases, 12 from diphtheria, 11 from scarlet fever, and 3 from whooping-cough, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 1·8, against 1·0 per 1000 in the 96 large English towns. The deaths attributed to measles, which had been 35, 40, and 36 in the three preceding weeks, rose to 39 in the week under review, and included 16 in Glasgow, 5 in Paisley, 4 in Edinburgh, 3 in Leith, and 3 in Kirkcaldy. The deaths of infants under 2 years referred to diarrhœa and enteritis, which had been 8, 14, and 13 in the three preceding weeks, were 14, of which number 6 occurred in Glasgow, 2 in Edinburgh, and 2 in Hamilton. The fatal cases of diphtheria, which had been 14, 12, and 17 in the three preceding weeks, declined to 12, and included 4 in Aberdeen, 3 in Glasgow, and 2 in Greenock. The deaths attributed to scarlet fever, which had been 11, 8, and 12 in the three preceding weeks, were 11 in the week under review, and included 5 in Glasgow and 3 in Kilmarnock. The 3 deaths referred to whooping-cough were slightly below the average in the earlier weeks of the quarter, and were recorded in Glasgow, Greenock, and Kirkcaldy respectively.

The deaths referred to diseases of the respiratory system, which had been 129, 123, and 157 in the three preceding weeks, declined to 139 in the week under notice; 32 deaths resulted from different forms of violence, against 23 and 30 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,199,180 persons at the middle of 1913, 529 births and 435 deaths were registered during the week ended Saturday, Dec. 20th. The annual rate of mortality in these towns, which had been 16·6, 16·0, and 17·7 per 1000 in the three preceding weeks, further rose to 18·9 per 1000 in the week under notice. During the first 12 weeks of the December quarter the mean annual death-rate in these Irish towns averaged 17·3 per 1000; in the 96 large English towns the corresponding rate did not exceed 13·8, while in the 16 Scotch towns it was equal to 15·4 per 1000. The annual death-rate in the week under review was equal to 20·3 in Dublin (against 14·7 in London and 17·6 in Glasgow), 18·6 in Belfast, 23·1 in Cork, 11·4 in Londonderry, 17·6 in Limerick, and 34·2 in Waterford, while in the 21 smaller towns the mean death-rate did not exceed 12·8 per 1000.

The 435 deaths from all causes were 28 in excess of the number in the previous week, and included 36 which were referred to the principal epidemic diseases, coinciding with the number recorded in each of the two preceding weeks. Of these 36 deaths, 11 resulted from infantile diarrhœal diseases, 8 from scarlet fever, 8 from diphtheria, 6 from whooping-cough, 2 from measles, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·6 per 1000; in the 96 large English towns the corresponding rate did not exceed 1·0, while in the 16 Scotch towns it reached 1·8 per 1000. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 12, 13, and 6 in the three preceding weeks, rose to 11 in the week under review, and comprised 8 in Dublin, 2 in Galway, and 1 in Belfast. The deaths referred to scarlet fever, which had been 5, 13, and 8 in the three preceding weeks, again numbered 8, of which 5 occurred in Belfast and 3 in Dublin. The 8 fatal cases of diphtheria, of which 6 were registered in Dublin, coincided with the number recorded in the previous week. The 6 deaths attributed to whooping-cough were 2 in excess of the average in the earlier weeks of the quarter, and included 3 in Belfast. The fatal cases of measles were recorded in Dublin and Galway respectively, and that of enteric fever in Dublin.

The deaths referred to diseases of the respiratory system, which had been 76, 73, and 92 in the three preceding weeks, fell to 80 in the week under notice. Of the 435 deaths from all causes, 136, or 31 per cent., occurred in public institutions, and 5 resulted from various forms of violence. The causes of 18, or 4·1 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death did not exceed 0·5 per cent.

THE SERVICES.

THE FOOD REQUIREMENTS OF THE BODY IN ACTIVE SERVICE.

An important contribution to the study of practical [illegible] officers in medical charge and for the purpose of taking scientific observations. The marching took place on Salisbury Plain between Oct. 10th and 23rd, the weather conditions [illegible] in these [illegible] total average Calorie value bei [illegible] the first week 13 men gained and 7 lost weight; in the second week only 2 men gained and the remainder lost. The average gain in the first week was 0·32 kg.; the average loss in the second week 1 kg. For the whole period 5 men gained and 15 lost weight, the balance of loss being 0 69 kg. per man; that is, the difference between the averag [illegible] (64·15 kg.) and at the end of th [illegible] increase in weight during the fir [illegible] to have been due mainly, if not ent [illegible] in some form, probably in musc [illegible] last five days of the experiment [illegible] loss of 234 grammes (about ½ lb.) i [illegible] and of 334 grammes (about ¾ lb., [illegible] officers. This was not due only, or chiefly, to diminution of fat, bu [illegible] The loss [illegible] in the h [illegible] the ration supplied, especially in the amount of fat. The [illegible] position of the field [illegible] e different food con- [illegible] potatoes (weighing [illegible] ould be substituted [illegible] cheese, 2 oz. dried peas, beans, or lentils (or 2 oz. oatmeal), 3 oz. coffee, milk, and sugar (in block form), and 4 oz. jam (additional to the [illegible]

[illegible] major and 5 men of the Royal Army Medical Corps, with a regimental officer, an Army Service Corps officer, and three officers of the Royal Army Medical Corps. On each occasion the men were volunteers, and received a consideration of 1*s*. 6*d*. a day for their [illegible] it of the previous [illegible] ible) worse. The [illegible] being pitched at [illegible] day, and almost [illegible] temperature was [illegible] unsheltered, the site peaty. In spit [illegible] behaviour of the m [illegible] experiment loyally [illegible] party was very go [illegible] (probably due to c [illegible] In addition to the [illegible] of bacon, of cheese, [illegible] tea, sugar, and jam very slightly increased. In this dietary during [illegible] fat 142 [illegible] hat work of the march [illegible] 1900 (3034 Calories) the [illegible] whole period was experienced by 10 of the men, 8 lost weight, and 2 made up in the second week for loss of weight during the first. The increase in protein, fat, and carbohydrate provided during the second march is considerable when compared with the corresponding amounts is[illegible] during the first march; and the total average Calorie valu[illegible] (4511) of the second is 30 per cent. higher than that of the first dietary (3465). The appearance of the men was strikingly different on the second occasion. No man showed any sign of wasting, no hollow cheeks, no sunken eyes. The first expedition was (unofficially) known amongst the troops as the "hunger march," which aptly expresses the view of the rank and file; but after the second march a considerable number of men expressed regret that it was not going to extend over another fortnight. The report must be consulted for details of weights, distances, food quantities, &c., all of which are set out in an admirably clear and complete manner. It is satisfactory to learn from the preface that the Army Council have approved of the field service ration (weighing 3 lb. and yielding 4500 Calories) recommended by the committee, and have directed that experiments in lightening the equipment should be continued.

ROYAL NAVY MEDICAL SERVICE.

Fleet-Surgeon Cyril James Mansfield, M.V.O., has been promoted to the rank of Deputy Surgeon-General in his Majesty's Fleet (dated Sept. 27th, 1913).

The following appointments have been notified:—Fleet-Surgeon: H. B. Maryiott to the *Egmont*. Staff-Surgeons: J. J. H. Rooney to the *Albemarle*; J. D. Keir to the *Natine*, and on recommissioning; and P. T. Sutcliffe to the *Hindustan*. Surgeons: C. M. R. Thatcher to the *Victory*, additional, for long course of physical training; and G. B. Cockran to the *Europa*, for voyage out and home.

ROYAL NAVAL VOLUNTEER RESERVE.

The rank of Surgeon Probationer in the Royal Naval [illegible] 2*s*. a day.

ARMY MEDICAL SERVICE.

[illegible] C.M.G. [illegible]

ROYAL ARMY MEDICAL CORPS.

Major James C. Jameson to be Lieutenant-Colonel, vice [illegible]

[illegible] for appointment [illegible] East Indies, vice [illegible] pointed Deputy [illegible] tish Command.

[illegible] en appointed to [illegible] ment, vice Major J. Smith.

[illegible] pital, Woolwich, vice [illegible] C.S.I. Lieutenant- [illegible] for the increased rate [illegible] Warrant. Lieutenant-Colonel J. Girvin has arrived home for duty from Ahmednagar Cantonment. Lieutenant-Colonel H. E. Winter and Lieutenant-Colonel G. A. T. Bray have exchanged positions on the roster; the latter officer will remain on the Home Establishment. Lieutenant-Colonel T. G. Lavie has arrived [illegible] for duty from [illegible] ed under orders for a tour of duty in Jamaica. Major A. W. Sampey has been appointed to hold medical charge of the Enteric Fever Convalescent Depôt at Wellington Cantonment, Madras Presidency. Major H. F. Shea has been selected for appointment as Specialist in Advanced Operative Surgery to the Lahore Division of the Northern Army in India. Major B. Watts [illegible] Major [illegible] O.B. [illegible] ent of [illegible] ation) [illegible] Command. Major C. H. Hopkins has taken over medical charge at Devizes. Major B. F. Wingate has been appointed to the London District for duty.

Captain T. S. Dudding has embarked for India. Captain A. W. Byrne has been selected for appointment as Deputy Assistant Director of Medical Services (Sanitary to the

Lahore Division of the Northern Army in India. Captain J. A. Turnbull has been appointed to hold charge of the Military Hospital at Kamptee Cantonment. Captain J. J. O'Keefe has arrived home for duty from India. Captain D. E. Curme has been transferred from Aldershot to the Northern Command for duty at York. Captain A. Hendry has arrived home from the Military Hospital at Colaba, Bombay, on general leave of absence. Captain N. E. J. Harding has been selected for appointment as Medical Officer to the Tower of London. Captain K. A. C. Doig has embarked for service in India. Captain H. W. Russell has been placed in charge of the Bacteriological Research Laboratory at Brigade Headquarters of the Sirhind Brigade at Ambala Cantonment. Captain M. B. H. Ritchie has been appointed for duty at the Military Hospital, Colchester. Captain W. Benson has been transferred from the Royal Herbert Hospital at Woolwich to the Aldershot Command. Captain J. A. W. Webster has embarked for a tour of duty in India. Captain T. H. Dickson has arrived home on general leave of absence from the Military Hospital at Gibraltar. Captain W. B. Purdon has taken up duty at the Military Hospital, Belfast. Captain P. Power has embarked for a tour of service in India. Captain E. L. Moss has been transferred from Salisbury Plain to the Portsmouth District. Captain A. E. F. Hastings has taken up duty at the Military Hospital, Chatham. Captain J. du P. Langrishe has been appointed to the Irish Command. Captain W. D. C. Kelly has taken up duty at Pretoria as Specialist in Advanced Operative Surgery. Captain G. W. W. Ware has been transferred from the Military Hospital at Youghal to Kilkenny. Captain G. De la Cour has taken up duty at the King George V. Military Hospital, Dublin. Captain E. W. M. Paine has joined at Manchester for appointment as Recruiting Medical Officer on the Staff. Captain M. Keane has been transferred from Warwick to [illegible] al at Bulford Camp, Salisbury Plain. [illegible] ns have joined the Royal Army Medical [illegible] for the courses of instruction for pro- [illegible] f Major:—F. A. McCammon, A. Dawson, F. Forrest, V. C. Honeybourne, V. G. Johnson, C. R. M. Morris, R. E. U. Newman, E. W. M. Paine, and J. B. Grogan.

INDIAN MEDICAL SERVICE.

The King has approved of the promotion of Major George Yeates Cobb Hunter to Lieutenant-Colonel (dated Nov. 17th, 1913).

The King has approved of the retirement of the following officers:—Colonel Alfred Woodrow Stanley Wingate (dated Dec. 19th, 1913) and Lieutenant-Colonel Edward Ross Morton (dated Nov. 27th, 1913).

Surgeon-General Sir C. Pardey Lukis, K.C.S.I., has been appointed an additional member of the Imperial Legislative Council, vice Surgeon-General A. M. Crofts, C.I.E., resigned.

Colonel J. Crimmin, V.C., C.B., C.I.E., has been selected for appointment as Assistant Director of Medical Services to the Derajat and Bannu Brigades, in succession to Colonel E. B. Grayfoot, transferred. Colonel P. Hehir has been transferred from the Burma Division to the Sixth (Poona) Division of the Southern Army, and appointed Assistant Director of Medical Services, vice Surgeon-General T. M. Corker, transferred to Secunderabad.

Lieutenant-Colonel A. W. T. Buist has taken up duty at Campbellpore as Superintendent of the District Jail, vice Captain H. C. Keates, transferred. Lieutenant-Colonel G. McI. C. Smith, civil surgeon, has been appointed to Ludhiana, relieving Captain A. K. Lauddie, transferred. Lieutenant-Colonel C. N. C. Wimberley has been selected for appointment as Deputy Assistant Director of Medical Services (Mobilisation) to the Secunderabad Division, vice Lieutenant-Colonel D. D. Shanahan, tour expired. Lieutenant-Colonel G. B. Irvine has arrived home on general leave of absence from India. Lieutenant-Colonel G. Bidie has been granted an extension of leave of absence home from India.

Major W. R. Battye has been selected for appointment as Residency Surgeon at Mewar State. Major H. J. Walton has been selected for appointment as Professor of Pathology on the staff of King George's Medical College at Lucknow. Major W. Glenn Liston, director of the Bombay Bacteriological Laboratory, has been appointed to act as Senior Member of the Plague Research Commission. Major S. R. Christophers has been appointed to officiate as Director of the Central Research Institute at Kasauli during the absence on special duty of Major W. F. Harvey. Major J. W. Watson has been selected by the Foreign Department of the Government of India for appointment as Agency Surgeon in the State of Bhopal. Major G. McPherson has been appointed Presidency Surgeon, Second District Bombay, and to hold medical charge of the Common Prison, the House of Correction, and the Byculla Schools. Major E. C. MacLeod has been selected for appointment as Civil Surgeon at Darrang, Assam. Major W. H. G. Forster has arrived home on combined leave of absence from India. Major A. Gwyther, civil surgeon at Rajshahi, has been appointed for temporary duty under the Director-General, Indian Medical Service. Major H. A. J. Gidney, civil surgeon in charge of the Naga Hills District, has been appointed to Delhi in connexion with anti-malarial prevention. The services of Major A. C. MacGilchrist have been placed temporarily at the disposal of the Education Department of the Government of India. Major D. McCay has been granted leave of absence for seven months.

The services of Captain G. Holroyd have been placed at the disposal of the Lieutenant-Governor of the United Provinces of Agra and Oudh by the Government of Bengal, to officiate as Superintendent of the Central Prison at Bareilly, vice Captain J. F. Boyd. Captain F. H. Salisbury has arrived home on leave of absence from India. Captain H. G. Stiles Webb has been appointed for duty to the Sanitary Department of the North-West Frontier Province. Captain R. B. Lloyd has been appointed to officiate as Chemical Examiner to Bengal Presidency and Professor of Chemistry in the Government Medical College at Calcutta. Captain T. J. C. Evans has keen appointed to hold civil medical charge of the Manipur State. Captain R. T. Wells has been transferred from Lahore to Jullundur and appointed Plague Medical Officer. Captain C. A. Gill, officiating civil surgeon, has been appointed Chief Malaria Medical Officer in the Punjab on return from leave in succession to Captain H. G. Stiles Webb. Captain M. J. Holgate has been appointed provisionally to hold charge of the Cantonment General Hospital at Quetta, vice Major G. Brouse. Captain B. E. M. Newland has taken up duty at Etawah. Captain J. O'Leary has arrived home on general leave of absence from India. Captain F. R. Coppinger has been appointed Staff-Surgeon at the Crater, Aden, in addition to his other duties, vice Captain E. D. Caddell, R.A.M.C.

Lieutenant B. F. Eminson has been appointed to officiate as medical officer to the 127th Queen Mary's Own Baluch Light Infantry.

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd East Anglian Field Ambulance, Royal Army Medical Corps: Captain James M. G. Bremner to be Major (dated Nov. 5th, 1913).

2nd Western General Hospital, Royal Army Medical Corps: Lieutenant-Colonel Graham Steell resigns his commission (dated Dec. 24th, 1913).

1st London Divisional Clearing Hospital, Royal Army Medical Corps: Major Alexander Barclay Lyon, from the List of Officers attached to Units other than Medical Units, to be Lieutenant-Colonel (dated Nov. 28th, 1913).

Attached to Units other than Medical Units.—Captain Edward R. Williams resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Dec. 24th, 1913).

Major Richard C. M. Pooley is retired, under the conditions of paragraph 116 of the Territorial Force Regulations, and is granted permission to retain his rank and to wear the prescribed uniform (dated Dec. 24th, 1913).

THE MEJIDIEH DECORATION.

A special order of the Egyptian army issued by the Sirdar from headquarters (Khartoum) on Nov. 17th mentions that El Bimbashi C. Cassidy (Captain R.A.M.C.) has been brought to the notice of the Khedive for good service in connexion with recent operations against the Ajaakir tribe. The Khedive subsequently conferred the fourth class Mejidieh decoration on El Bimbashi C. Cassidy in connexion with the operations mentioned.

DONATIONS AND BEQUESTS.—In accordance with the wishes of the late Dr. C. Theodore Williams his widow has sent a cheque for £1000 to the Brompton Hospital for Consumption, to name a ward to his memory.—The late Mrs. Sarah Berry, of Wimbledon, has bequeathed £1000 to the Royal Hospital for Incurables at Putney.—By the will of the late Mr. R. Bayly, of Bideford, the South Devon and East Cornwall Hospital and the Royal Albert Hospital, Devonport, will receive £500 each, and the Leominster Cottage Hospital £100.—The late Mrs. E. S. Millar, of Belfast, has bequeathed £500 to the Royal Victoria Hospital, Belfast, and £200 each to Homes for the Blind, Cliftonville, Society for Providing Nurses for the Sick Poor, Ulster Hospital for Children and Women, Belfast Hospital for Sick Children, and Forster Green Hospital for Consumption and Chest Diseases.—By will the late Mr. R. H. Hooker, of Weston-super-Mare, has bequeathed £1000 to the Church Missionary Society for the maintenance of its medical hospital at Srinagar, Kashmir. Subject to one life interest he left £500 to the Weston-super-Mare Hospital, and the ultimate residue of his property, subject to various legacies and annuities, he left to the Church Missionary Society for the maintenance of its medical missions.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from Vol. II., 1913, p. 1798.)

XXXII.—INSURANCE PROBLEMS IN GERMANY COMPARED WITH THOSE IN ENGLAND.

DURING the past summer I made it my business to look into the working of the German insurance legislation on the spot, which was the easier for me since I was already familiar with the problems. The influence of the German example is known to have been strong upon the framers of the British Acts. Other writers have made valuable comparisons in THE LANCET and elsewhere between the British and German conditions, but these first-hand observations may well be introduced here and now, at the commencement of the second year's consideration of medical practice under our own Insurance Act.

Medical Strikes in Germany.

Though in some respects quite different, there are several points of close resemblance between the practical effects and the difficulties created by the German law for compulsory insurance and those resulting from the British Insurance Act. A few months ago I was able to call at the offices of the Verband der Aerzte Deutschlands at Leipsic. Here I was cordially received by Dr. J. Hartmann, the general secretary of this great medical union, which counts more than 25,000 members. I soon found that many of the situations which had forced the medical practitioners of Germany to form a fighting union, with strike funds, were the same or very similar to those that exist in England. Of this I had already previous knowledge. In 1909 I went to Cologne to describe the great medical strike which was then taking place in that town.[1] Some 80 practitioners had revolted against their conditions of employment by the societies carrying out the insurance law. They claimed that the patients should have the right to the free choice of doctor, and that no practitioner should be allowed more than 2000 insured persons on his list. Earlier than this, viz., in 1904, there was a medical strike for similar reasons. The societies formed by the insured, the sick club or *Cassa* as they are called, had imported as strike breakers 32 or 35 practitioners. But on this occasion the Government took sides with the medical profession, declared that the societies had not a sufficiently numerous medical staff to attend to all the persons insured, and that they must come to an agreement with the local practitioners. The strike of 1904 proved, therefore, quite successful, and an agreement for five years was concluded. It was because the societies would not renew this agreement of 1904 that the second strike broke out in 1909. It did not prove successful, because the *Cassa* was able to secure the services of a sufficient number of medical officers, and therefore each doctor had a reasonable number of insured persons on his list. In England, in all the large centres the same grievance may arise for the local profession. In several cities certainly there are two, three, or more panel doctors who have 3000 to 4000 insured persons on their lists. This is considered a danger by both medical men and the public, and one that may become an abuse; and there is a general feeling that something should be done to prune such superabundant lists. As the German Government had intervened at Cologne when these lists comprised more than 2000 insured persons I recalled these circumstances to Dr. Hartmann, and inquired if the law, or the regulations for applying the law, in Germany established a limit to the number of persons that any one practitioner should accept on his list. His reply was to the point.

The German Government and a Limit to the Panel List.

Dr. Hartmann said there was no law, but that a tacit understanding existed that 2000 names were enough on one list; and that when in 1904 this number was greatly and often exceeded, the Government did interfere, so that many persons then imagined there was some clause in the law establishing a limit. As a rule, the insurance societies or the officials of the *Cassa* recognise the need of a limit; still, if one such organisation did allow a doctor to have a very long list no legal action against anyone could be taken. The notion also that a doctor could have a very long list and make a sub-contract with an assistant to do a portion of the work, and thus establish a sort of sweating system, does not trouble the organised members of the medical profession in Germany. Such cases do exist, but they are few and far between. The Verband, of course, sets its face against them. Such matters are generally regulated by the agreements drawn up between the Verband on behalf of the medical profession and the *Cassa* on behalf of the insured, and both sides are interested in preventing sweating and in not allowing any practitioner to have more patients than he can properly attend upon. Thus it may be said that, though there is no legal enactment, the general feeling, both of the medical profession and of those who administer the insurance funds—i.e., the society or *Cassa*—is distinctly opposed to sub-contracts which may lead to the sweating of medical men, and does not approve the allocation of more than 2000 insured persons to any one practitioner.

These are two very important points bearing on the working of the Insurance Acts in England. At first it was understood with us that panel doctors should not be allowed to send assistants to attend their patients. Then the idea got about that this might be done; but, on the other hand, the patient might object, and in that case the objection would be held as valid. Another interpretation was that if a panel doctor employed an assistant, the assistant, to attend insured patients, must have his name on the panel and have been selected by those patients; consequently they became his patients and not his employer's patients. The whole matter in England is still ill-defined; but the opponents of the sweating system, whether the sweater concerned be himself a medical man or not, will find in Germany an inspiring example. Those also who think that it tends to the degradation of medical science for a panel doctor to have too many insured persons on his list will likewise derive from the German custom and example considerable encouragement. It is no small matter to know that in these questions the powerful Leipziger Verband is on their side. The fact that in 1904 the German Government interfered at Cologne because there were more than 2000 persons on some of the lists the Medical Service Board was a weighty one, and it seemed advisable that they should consider forthwith how far they could unite with other public bodies in presenting a coherent and well-articulated scheme to the Board. Dr. Robertson went on to say that from a long and intimate knowledge of the county of Inverness he was convinced that public opinion was growing more and more to be in favour of larger areas for several of the big public services of the county. He considered medical service an outstanding case in point. In the present stage of administration the county might be considered the best large unit they could get, and he thought that a scheme of a great advisory medical committee for the whole county, containing representatives of the public health authority, the county national insurance, the school board system, and representatives of the medical practitioners and of the nursing agencies, would be well worth prompt consideration. The decisions of such a body would have weight with the Medical Service Board, in so far as that they would be able from their local knowledge to produce or recommend county, district, or parish schemes that would tend to economy and efficiency in the working. In view of an early meeting of the county council, representatives were appointed from the County Education Committee to ask the county council to draft a scheme under its own auspices, in which case they, if duly represented in the central body, would be glad to coöperate.

[1] THE LANCET, July 31st, 1909, p. 324.

Adulteration of Milk in Glasgow.

According to the report from the corporation of Glasgow's chemical department, during the past year there were examined 332 samples of sweet milk, 19 of cream, and 19 of skimmed milk. Of sweet milk 97 samples, of cream 2, and of skimmed milk 2, were adulterated. Of the sweet milk samples 67 per cent. were certified as adulterated solely on account of deficiency in fat, apparently resulting from the artificial reduction of the quality of sweet milk by the admixture of separated milk. The only way to obviate this practice was to get the official sanction of the Board of Agriculture to make compulsory the labelling of separated milk as such. The report also suggested the extension to Scotland of the Public Health (Milk and Cream) Regulations, 1912. The form of adulteration of butter most difficult to detect was the addition of small quantities of animal fat. Of the 247 samples of butter submitted 27 were certified as adulterated from this cause.

Airdrie Sanatorium Question.

At a special meeting of the Airdrie Town Council last week it was decided to provide a local tuberculosis sanatorium for the town itself, rather than to enter into a joint scheme with other Lanarkshire burghs. The Local Government Board will be so notified, though the precise nature of the scheme has yet to be determined.

Territorials and the City Hospital, Aberdeen.

The secretary to the City of Aberdeen Territorial Force Association has sent a letter to the public health committee asking whether, in the event of mobilisation, an arrangement could be made with the council whereby beds in the city hospital could be provided for infectious cases. A reply has been given that the council, without recognising any obligation as to reserving a specified number of beds, is ready to make such arrangements as it can for army cases consistent with meeting the more pressing needs of the city itself, and it is added that there is every likelihood that at least one pavilion, accommodating 40 to 50 patients, could be made available.

Dinner to Dr. Melville Dunlop.

Recently Dr. Melville Dunlop was entertained to a complimentary dinner by his colleagues and old resident physicians in the Caledonian Station Hotel on the occasion of his retirement from the staff of the Royal Edinburgh Hospital for Sick Children, with which he has been connected for 27 years. Mr. Harold J. Stiles presided over a large company, and in making a presentation of some handsome silver plate spoke of the affection and esteem which were universally entertained for Dr. Dunlop and of the valuable services he had rendered both as a teacher and as a physician to the hospital. Dr. Dunlop, in an interesting speech, sketched some of the changes and developments which had occurred during the long period he had been associated with the hospital.

Dec. 29th, 1913.

IRELAND.

Venereal Disease in Dublin.

THE figures given by Sir William Thompson Registrar-General, before the Royal Commission on Venereal Diseases[1] give rise to some cause for question. Sir William Thompson stated that the death-rates from syphilis and general paralysis o the insane were in Dublin abnormally high, being about twice those of London. It is probable tha the incidence of venereal disease in Dublin i high, and this is in great part explained by the presence of an unusually large number o soldiers in proportion to the civil population The incidence is not, however, so high as might be assumed from a consideration o the death-rate alone. The accuracy of the officially recorded death-rate depends on the accuracy with which the primary cause of death is stated in death certificates. In the case of a death from venereal disease occurring in private practice, it is but rarely that the fact appears on the death certificate, which, as a rule, has to pass through the hands of near relatives of the deceased. The death-rate from venereal disease is, therefore, probably much higher as regards persons attended in private practice than the official returns show. This error does not come in, however, in the case of persons who die in public institutions. In Dublin nearly half the deaths occur in public institutions, a much higher proportion than in any other city in the kingdom The statistics for Dublin as regards venerea disease approach, therefore, more nearly to accuracy than the statistics for London or other large towns.

The National Insurance Act.

The Irish Medical Committee, who have been negotiating with the Irish Insurance Commissioners, have requested the various Local Medical Committees to obtain guidance from the Central Committee on the following questions: In case of appointment of more medical referees, should these be selected by the Irish Insurance Commissioners on the nomination of the various Local Medical Committees, or should the Friendly Societies have the right to choose them as required? Further, should they be part- or whole-time officers?

---

[1] THE LANCET, Dec. 27th, 1913, p. 1874.

Belfast Union Workhouse.

Mr. F. J. McCarthy, Local Government Board inspector, has just sent to the Belfast guardians a copy of his report consequent on his recent inspection of the workhouse. From it we find the gratifying intelligence that there had been a reduction of 30 per cent. in the number of workhouse inmates during the past five years, the number of inmates on Saturday, Nov. 8th, 1913, in the workhouse (including the sanatorium at Whiteabbey) being 2898, *instead of* 4139, *on* Nov. 14th, 1908. As regards the management and cleanliness of the institution the inspector speaks very favourably. "Due order was maintained among all classes, and care was taken that the workhouse rules regarding classification were strictly observed." He found the sanatorium for consumptives at Whiteabbey, "as on previous occasions, a model of neatness, cleanliness, and orderliness." The inspector draws special attention to the reduction of cases treated in the maternity hospital in the workhouse since the coming into operation of the National Insurance Act, 1911. For the year ended Sept. 30th, 1912, the total number of births in the union maternity hospital was 405, while in the following year it dropped to 281. The inspector, in concluding his most complimentary report, bears testimony to the "care and attention which the guardians, through their numerous committees, devoted to the work of administration. Lady members of the board took a deep interest in the work of the committees dealing with the sick and of the children under the guardians' charge. Credit was also due to the officers, and in particular to the clerk and master, for the efficient manner in which they discharged their duties."

Certifying Factory Surgeon.

Mr. W. McLorinan, L.R.C.P. & S. Irel., visiting physician to Mater Infirmorum Hospital, Belfast, has been appointed Certifying Factory Surgeon for North Belfast, in place of Dr. J. E. MacIlwaine, resigned.

PARIS.

The Léon Bourgeois Dispensary.

THE name of M. Léon Bourgeois, to whose efforts much social legislation in France is due, and particularly the antituberculosis laws, has been given to a new dispensary established in the gardens of the Hôpital Laennec. This dispensary has three divisions—one devoted to the hospital care of patients, another to consultation, and a third, the essential element of the institution, to a preventorium. This last consists of rest and fresh air galleries where poor people whose condition does not demand confinement to bed pass the day or part of it in rest and superalimentation, returning at night to their homes, of which the sanitary condition is controlled by frequent visits from the dispensary officials. The plan has met with enthusiastic support from the population, constituting, as it does, a middle course between sanatorium and domiciliary treatment. It affords the necessary rest and alimentation to tuberculous patients still able to work, while permitting them to earn something for the support of their families, for they spend only so much time as is necessary daily in the preventorium. The inauguration of the dispensary was the occasion of an official ceremony at which the President of the Republic, as well as M. Léon Bourgeois, was present. The President seized the opportunity to explain the antituberculosis programme of the Assistance Publique of Paris. This consists of dispensaries for out-patient consultations; the distribution of aid in kind and money, and the inspection of dwellings; the provision of preventorium treatment; the reservation of special quarters for the tuberculous patients in certain of the Paris hospitals, and the establishment of a suburban hospital for the tuberculous, the construction of which is about to be begun in the neighbourhood of Paris.

The General Mortality in France.

According to the recently published report of M. Mirman, Directeur de l'Assistance et de l'Hygiène Publique in the Ministry of the Interior, for the year 1911—a particularly fatal year in nearly all European countries—the total deaths in France were 775,088, equal to a death-rate of 19·59 per 1000, a total increase of 70,318 over the preceding year. The increase was mainly among children under one year and people over 60, the excess in the former group being 30,172, in the latter 26,410. Enteritis was the predominant factor in the first group, carrying off 46,769, or nearly half of the total number (118,300) of deaths in children under one year, an increase of 28,631 over the preceding year. Typhoid fever showed an excess of 1324 deaths in 1911 over the mean of the preceding years, probably due to the excessive heat, which diminished the supply of pure drinking water and also led to the consumption of impure ice. Epidemic diseases showed a general decrease. Influenza, the most fatal, caused 9600 deaths. The total deaths from epidemic diseases were much the same as for deaths from violence and suicide—viz., 29,470, as against 29,163. This indicates that even when hygienic prophylaxis shall have achieved its utmost, much will remain to be done. The epidemic diseases, against which the greatest effort is being made in France to-day, contribute only 4 per cent of the total number of deaths, and this figure is declining with the measures that are being taken against typhoid fever by the provision of an increased supply of drinking water and its protection against contamination, as well as by antityphoid inoculation. Cancer and tuberculosis figures, however, remain disquieting. Cancer in 1911 claimed more victims than all the epidemic diseases put together—viz., 31,768. The condition calls for energetic action. Tuberculosis still claims the highest figure of all, notwithstanding its diminution from year to year. In 1911 it carried off 90,000 victims—that is to say, that between 20 and 40 years 44 per cent. of deaths are due to tuberculosis [illegible] ged against the [illegible] ns and in som [illegible] is still greatly lacking. The Senate is occupying itself with a Bill introduced by M. Léon Bourgeois, M. A. Ribot, and M. Paul Strauss for the establishment of a central bureau of social hygiene and of an antituberculosis office, the passing of which Bill is urgently required, as well as the law regarding cheap dwellings and for the expropriation of insanitary property. M. Mirman, in closing his report, directs attention to the mortality due to alcoholism, still a great scourge in France, and an active factor in tuberculosis, as well as in deaths due to violence and those of children caused by congenital debility.

The Centenary of Claude Bernard.

The centenary of Claude Bernard, who was born on July 12th, 1813, was celebrated by a commemorative ceremony at the Collège de France on Dec. 23rd, in the presence of the President of the Republic and a numerous assembly of the scientific world. M. M. Croiset spoke of the lustre that Claude Bernard, who was professor of physiology there, had reflected upon the college. Professor Bergson told of the influence that the books of Claude Bernard and his conception of life had had upon the spirit of his age. Professor Dastre described the works and the numerous discoveries of Bernard, particularly those relating to the physiology of digestion, and Professor d'Arsonval spoke in the name of the former pupils of the master. The Minister of Public Instruction, in a striking address, described France's debt to the *savant* who began his illustrious career as the humble assistant in a pharmacy at Lyons, came to Paris with a view to getting a tragedy put upon the stage there, and entered the laboratory of Magendie at the Collège de France, finally succeeding him in the chair in 1855. He died at Paris on Feb. 10th, 1878.

Dec. 29th, 1913.

BERLIN.

The Battle of the Clubs.

THE possibility that a sick club may be unable to obtain medical attendance for its members at the usual club rates has not been overlooked in the new Workmen's Insurance Act. It does not appear that the patients need suffer any detriment, for an alternative is indicated in a portion of the Act which provides that in such circumstances the members may receive sick pay in excess of the ordinary allowance for the purpose of enabling them to consult practitioners unconnected with the club. Before making these increased payments, however, the club must obtain permission from the district insurance office, which has also to decide how a patient's inability to follow his employment may be certified when an arrangement for that purpose cannot be made with a medical man. The federal council has recently issued instructions to the district insurance offices informing them under what conditions they may allow the committees of the sick clubs to pay the higher sick rate instead of procuring free medical attendance. It is stated in the instructions that the above provision may only come into force when the local medical men have declined to accept the arrangements proposed by the clubs. When no medical man is willing to give a certificate of illness to the club members, such certificates may be given by non-medical managers of the club, employers, midwives, nurses, or other trustworthy persons. In reference to this the *Medical Reform* rightly observes. What is the use of medical men devoting five years to professional study and passing several examinations when mayors, employers, and "other trustworthy persons" not possessing any medical knowledge may give certificates as to the condition of patients?

Eighteen Laparotomies on one Subject.

Dr. Harzbecker lately showed before the Berlin Surgical Society the case of a patient, 44 years of age, who in 1887 sustained a contusion of the abdomen in consequence of a fall from a horse. The sequelæ of the injury were frequent attacks of ileus, and as many as 18 laparotomies had been performed—the last one five years ago—without a definite cause for the ileus being found. In 1903 colostomy was performed, and finally an anastomosis between the cæcum and the sigmoid flexure was made. Recently he was treated only by electric light baths, enemata, physostigmine, and morphine. Dr. Harzbecker said that the symptoms were obviously due to chronic enterospasmus from a nervous cause, and that it was doubtful whether this condition was the result of the accident or not. The patient had been taking alcohol and morphine in excess since the accident.

Agitation respecting Degrees in Dentistry.

The dental students of the University of Leipsic have decided to engage in a so-called "strike," the reason being that their request for the creation of a degree of Doctor of Dental Surgery has been refused. They have telegraphed to the dental students of other universities to follow their example, and those of the University of Berlin have held a meeting of sympathy, at which it was decided to send delegates to Leipsic for the purpose of taking joint action. To understand the motives of the dental students it must be stated that a dental degree does not exist in Germany, although there is a State examination by which the title of "Zahnarzt" is conferred. Dentists wishing to have a university degree could not be examined by the medical faculties by which the title of M.D. is granted. This degree is obtained only after a regular study of medicine, but not of dental surgery, so the dental students have had to apply to the philosophical faculties where the title of Doctor Philosophiæ might be granted to them after an examination not including any reference whatever to dentistry. This undesirable state of things has led to repeated petitions being presented to the medical faculties and the Government to create the title of doctor of dental medicine or surgery, but these endeavours have hitherto proved unavailing, and the students hope to get by the "strike" what has been refused to less heroic measures. The "strike" has meanwhile extended to nearly all the German universities.

Dec. 24th, 1913.

ITALY.

Monument to Florence Nightingale in Florence.

FLORENCE, the city of the great Englishwoman's birth, has paid a rare tribute to the memory of Florence Nightingale. The British Ambassador, Sir Rennell Rodd, has unveiled in the cloister of Santa Croce, the church which represents to Italians what Westminster Abbey does to Englishmen, a monument to her memory. This is the work of an English sculptor, Mr. F. W. Sargant, brother of the learned judge and of the lady president of the Botanical Section of the British Association, and is a three-quarter life-size symbolical figure representing the "Lady with the Lamp," the name by which the heroine of the Crimea was known to the soldiers in the hospitals. The statue is a beautiful piece of work in the classical style, and has won unstinted praise. The idea of having a permanent record of Miss Nightingale in Florence originated with the British Consul-General in Tuscany at the time of her death. Money was raised by a public subscription, in which citizens of many nationalities joined, while the Deputazione dell' Opera di Santa Croce readily agreed to the suggestion that they should find a site for the monument. The military authorities and those of the province and city, with the Consular representatives, attended the unveiling ceremony, at which a large gathering of the foreign colony and of Italian society assisted. The Croce Rossa was largely represented by officials and lady members, and furnished a guard of honour of its *militi*. Two beautiful wreaths of flowers were presented by the ladies of the Croce Rossa, and placed one on each side of the statue. English nursing was well represented, among others by the Mothers Superior of the Little Company of Mary, the English order of nursing sisters, better known as the Blue Nuns. The British Ambassador, after unveiling the statue, pronounced an eloquent eulogy upon the work and character of Florence Nightingale, emphasising the long and careful training which were the prelude to her life's work. After thanking the authorities who had granted her a place in the precincts of their great shrine, he signed the *atto notarile*, handing the monument over to the care of the Opera di Santa Croce. The epitaph, the work of Senator Professor Isadoro del Lungo, must be given as a model for such work: "Florence Nightingale, MDCCCXX., L'eroina di Crimea, MDCCCCX., La Signora della Lampada, come la chiamarono i soldati che la ebbero infermiera mirabile nelle notti di spedale angosciose e fin d'allora animatrice colla virtù dell' esempio a quell' opera voluntaria di pietà internazionale che poi fu la Croce Rossa. Ha nella sua Firenze dove nacque e ne portò il nome gentile questo ricordo di venerazione e di affetto"—an inscription which sums up in a comparatively few lines the purpose of the monument and the history of its prototype. The statue in the cloister of Santa Croce will remain as a record of the international significance of her life. The ceremony of its unveiling forged another link in the friendship of England and Italy.

Higher Education in Italy.

The number of students of the universities has been gradually decreasing of recent years. From 21,492 in 1908 the number fell to 21,019 in 1909, 20,425 in 1910, and 19,772 in 1911, the last year for which statistics are available. The diminution has been greatest at Naples, Turin, Pavia, and Pisa, while there has been a slight increase at Bologna, Genoa, and Palermo. Naples continues to be the largest university with 4281 students, and Rome comes next with 2895. Turin holds the third place with 1800 students, but is likely to yield it soon to Bologna, which has already 1762. Next comes Palermo with 1511. At the end come Siena with 257, Cagliari with 227, Sassari with 262, and Messina with 87. At Messina, however, some of the faculties have been closed. There is an increase in the number of women students, of whom Turin has 167, Rome 155, Naples 105, Palermo 77, and Pavia 76.

Dec. 27th, 1913.

UNITED STATES OF AMERICA.

The New York Health Department.

Dr. Lederle, head of the health department of New York City, issued on Dec. 7th last a review of the work of that department during the past four years. In this period there has been, it appears from the report, a steady decline in the death-rate of the city. The death-rate for every 1000 of the population for the four years from 1909 was: 1909, 16; 1910, 15·98; 1911, 15·13; 1912, 14·11; and for the 48 weeks of 1913, 13·77. In 1912 the death-rate of Chicago was 14·68; Paris, 16·38; Berlin, 14·39; and London, 14·3. The reduction of infant mortality in New York during the four years has been remarkable, the rate of infant mortality having gone down from 137 in every 1000 in 1900 to 110 in 1912. The reduction in this direction is believed by Dr. Lederle to have been greater than that in any of the ten largest cities of the world, who attributes it largely to improvements of milk-supply. Among other matters mentioned in the report are the progress made in the enforcement of child hygiene and the extension of medical inspection in the schools. In 1912 six clinics for school children were established, free treatment being supplied to those who needed it. This year six dental clinics have been established. An interesting *résumé* of the departmental methods in combating infectious and contagious diseases and in improving those of food inspection is followed by a note on the value of vital statistics, and the necessity of prosecuting practitioners and midwives for failure to notify births. The report affords striking evidence of the energy displayed by the health department of New York during Dr. Lederle's directorship.

A Visit of English Surgeons.

A special clinic was arranged recently by Dr. William Seaman Bainbridge, professor of surgery at the New York Polyclinic Hospital and Medical School, when Sir W. Arbuthnot Lane, Mr. Herbert Paterson, and Dr. Bainbridge himself operated. Sir Arbuthnot Lane performed three operations. One was on an infant ten days old for the cure of cleft palate and hare lip; one was a short-circuiting operation on a patient suffering from intestinal stasis; and the third was a "plating" for fracture. Mr. Paterson did an exploratory laparotomy and Dr. Bainbridge a short-circuiting operation for intestinal stasis. In addition several persons who had been operated upon or treated by Sir Arbuthnot Lane and Dr. Bainbridge for intestinal stasis of varying degrees of severity were shown. Some of these had been operated on as long as five years ago, but all were in excellent health. The theatre in which the clinic was held was filled to overflowing, there being present surgeons from all parts of the United States. Among these may be mentioned Dr. John Wyeth, ex-President of the American Medical Association, ex-President of the New York Academy of Medicine, founder of the New York Polyclinic School of Medicine, and originator of post-graduate medical teaching in the United States.

In the evening a dinner was given to the English visitors at the St. Regis Hotel by Dr. Bainbridge. The guests, who numbered 120, and included representative members of the medical profession from all parts of the United States, heard Sir Arbuthnot Lane describe in detail the origin of his views and technique in dealing with intestinal stasis by operation. After Sir Arbuthnot Lane's address, pictures illustrating various stages of intestinal stasis were thrown on a screen, some of which were made from the X ray work of Dr. Alfred Jordan and some by a lady artist, procured for the purpose by Dr. Bainbridge, who knew nothing whatever of anatomy, and whose drawings, therefore, could only represent exactly what she saw, and not what she might think she ought to see. Great interest was shown by medical circles on the occasion, for, well known as Sir Arbuthnot Lane is on this side of the Atlantic, it was, I believe, the first occasion on which he has publicly expounded his views in detail.

Dec 20th, 1913.

SOUTH AFRICA.

Cape Medical Council.

As a consequence of the recent discussions at the Dental Society of the Cape Province, the Cape Medical Council has adopted a resolution objecting to the professional association of any registered medical or dental practitioner with any commercial firm, company, or association under any form of contract which constitutes such body an agency or intermediary deriving pecuniary advantage in connexion with the rendering of professional services to the public. The Council considers any medical practitioner or dentist associating himself in his professional capacity with any person, firm, company, association, or society which advertises or canvasses either personally or by means of agents for the purpose of procuring patients or customers, guilty of improper or unprofessional conduct. But these resolutions are not to apply to arrangements made by commercial bodies in respect of their own *bonâ-fide* employees, by shipping companies in respect of their passengers, or by hospitals or similar medical or dental institutions in respect of their patients. The committee of the Council recently appointed to consider the question of the certification of native and coloured nurses reported against the present advisability, in view of the requirements of the country, of instituting a lower grade nursing certificate for native and coloured persons. In a minority report Dr. A. J. Gregory differed entirely from the report of the majority. He was of the opinion that it was incumbent on the Council to make provision for the institution of a certificate for native and coloured nurses, obtainable after undergoing a suitable training and examination. After some discussion the matter was postponed until the next meeting of the Council, but it would seem clear that the Council is hostile to the view which is widely held in the country districts that there is need for a lower grade of trained nurse recruited from coloured or native people.

Railway Sick Fund Dispute.

Recently a deputation from the Natal Coastal Branch of the British Medical Association interviewed the Hon. H. Burton, K.C., the Minister of Railways, and Mr. W. W. Hoy, the general manager, on the subject of the rates of remuneration offered to railway medical officers by the South African Railway Sick Fund. The deputation pointed out that all the Friendly Societies in Natal paid their medical officers 12*s.* per head per annum. The members of these societies were working men, who had to find this money out of their own earnings. The sick fund, which was heavily subsidised by the Department out of public funds, was offering medical men little more than half of this amount. It was forcibly represented to the Minister that the Government was actually attempting to cut down medical earnings and asking the profession to work for less than the ordinary working man was already paying. The deputation also pointed out that their resistance was not entirely due to financial reasons; but that it was certain that if less money was paid for medical work, less time would be given to the work and the standard of medical service would be lowered. Mr. Burton stated in reply that in Natal medical services had in the past been remunerated at higher rates than in the other colonies. He pointed out that under Union the sick fund that had been in existence in the other provinces was being extended to Natal, and he stated bluntly that in his opinion the same rates of remuneration should be paid in Natal as had hitherto been paid elsewhere. He admitted that it was unfortunate for Natal that in this case it meant a levelling down of the rates to the standard of the Cape and other provinces, but he did not feel after fully considering all the circumstances that it could be avoided. At any rate, he was not prepared to interfere with the decision come to by the department. The deputation intimated to Mr. Burton that under these circumstances the posts advertised would be boycotted by the branch. So far the advances made by the Government towards a settlement of the dispute have not achieved much result, and resistance to the sick fund continues. Up to the present only one medical man in Durban has accepted the terms offered, the rest of the profession standing solidly together and presenting a united front for better terms.

Mental Asylum, Bloemfontein.

The Mental Asylum at Bloemfontein is about to be considerably enlarged as the result of the decision come to by Parliament last session. The additions will form part of a comprehensive scheme for providing additional accommodation for lunatics throughout the Union. The additions in question will be erected on the villa system, each villa to contain 40 to 50 patients. This system is unquestionably better suited to South African conditions than any other, though perhaps it is relatively somewhat costly to administer. When the additions are completed it is understood that the asylum will be provided with accommodation for some 2000 patients.

Criminal Investigation and Professional Secrecy.

A most unusual circular was recently distributed by the Criminal Investigation Department amongst Western Province practitioners. It stated that in a recent burglary a native, in endeavouring to open a safe, had part of a finger or thumb taken away, and requested any medical practitioner consulted by any native suffering from such an injury to telephone at once to the department. The circular has aroused a good deal of resentment amongst practitioners in the area on the ground that it asks them to commit a gross breach of professional etiquette.

Dec. 14th, 1913.

INDIA.

The Water-supply of the New Capital.

The provision of an ample water-supply at Delhi is of the highest importance, as with the increase in population, owing to the sojourn of the Government of India there during the winter and the preliminary operations connected with the new capital, the demand for water has largely increased. The municipality has, therefore, taken measures to improve and enlarge the existing supply. The purity of the water is beyond dispute, and altogether Delhi need have no anxiety about the quantity and quality of the water supplied to it under present conditions.

Stifling Railway Carriages in India.

Engineers in cold countries who have so successfully dealt with the heating of passenger trains can have but a small idea of the difficulty of cooling them in the tropics when the temperature is 165°F. or more in the sun and 115° in the shade. This is a difficult problem in India, as railway carriages may stand or travel empty in a blazing sun for hours completely shut up until they are literally soaked with heat. The traveller entering one of the vehicles in the summer has very often to choose between sitting in a storm of dust and smoke that enters by the open windows or stewing in a modified oven whose upholstery interferes with his chances of cooling even if he changes into a sleeping suit, which he can only do if travelling alone. Few people in Europe, even those who have travelled in the East, have any idea of the ingenuity that has already been expended on devices for reducing the temperature of the air in trains. Only a very small number of these methods have even been tried on any railway, as railway officers are alive to the fact that every addition of mechanism to a railway vehicle involves additional repair, and therefore additional expense.

The Milk-supply of Bombay.

The Bombay corporation is now discussing new by-laws which it will ultimately lay before the Government with the object of better regulating the stabling of milch cattle. This will do something to improve the Bombay milk-supply, but there is force in the argument that milch cattle should not be allowed on the island at all. There is plenty of suitable land in Salsette in proximity to the railway, and there would be no difficulty in bringing the supply in. The whole question ought to be scientifically approached, and it would probably pay a limited company with adequate capital to take up the enterprise. The corporation should recognise the fact that so long as it allows stables on the island there is little likelihood of anyone collecting cattle at a distance from Bombay. What the public must understand is that by-laws alone will not make a good supply. The trade itself should be directed with intelligence, knowledge, and skill.

The Cocaine Traffic in India.

The Bengal Excise Department recently threw into the Hooghly cocaine worth Rs.114,000 (over £7000 sterling), which formed part of various seizures on board ship and in the town of Calcutta. A better use might conceivably have been made of this confiscated cocaine.

An Overworked Hospital.

In a memorial on the subject of the Eye Hospital in Calcutta addressed to the Chief Secretary of the Government of Bengal, the Council of the European Defence Association declares that the institution in its existing state constitutes a grave scandal. This is not the fault of the hospital staff, who are making the best of exceedingly adverse conditions, and to whose efforts the council pays a deserved tribute. But the building, which may have been adequate for the purposes when it was erected, falls far short of the demands made upon it at the present day. The accommodation is utterly inefficient. The number of out-patients who present themselves for treatment averages 140 daily. In a large proportion of cases they can only be properly treated as in-patients, but there is no room for them. Many of these people travel long distances. Some have been known to walk over 100 miles to the hospital, and it is painful to learn that such pilgrimages were sometimes futile, and that sufferers whose sight could have been saved have become blind because of the impossibility of admitting them for treatment in the overcrowded wards. The absolute lack of accommodation for septic cases also is a serious drawback to good work.

Medical Instruction in Madras.

With the large programme of medical service for women now on the *tapis*, in which Sir Pardey Lukis is evincing particular interest, it is clear that men and women trained as medical practitioners must be provided in increasing numbers to meet the requirements of the Indian population. Even now the supply is inadequate to the demand, and this is particularly the case in Madras. The Madras Medical College has a deservedly high reputation for turning out efficient medical subordinates, but unfortunately it is the only medical institution in the presidency where instruction and training are given. In the last annual report of the Medical College the Government, on the recommendation of the Surgeon-General, has decided to admit for instruction only 80 students annually, so that any applicants in excess of that number must in future be refused. If there were any other institution to which this surplus of candidates could turn for instruction this would not much matter, but as it is, not only are useful careers balked, but the country loses services which it sadly needs.

Dec. 15th, 1913.

AUSTRALIA.

Small-pox in Sydney.

THE small-pox epidemic shows signs of self-exhaustion at last, and during the past five days only one case has been discovered. There are still some 150 persons in quarantine. Early in November a conference of health officials was held in Sydney to discuss the removal of the quarantine embargo placed on that city and its suburbs by the Federal authorities. The chief health officers of all the States were present, together with Dr. J. H. L. Cumpston, the Federal director of quarantine. An atmosphere of secrecy marked the proceedings. The press was not admitted, nor was any official statement issued. The conference unanimously agreed, it is understood, that on certain undertakings by the public health department of New South Wales the quarantine might be lifted, and future procedure in like cases was arranged. Communications have passed between various Governments, and the quarantine is to be lifted on Nov. 26th, although certain minor safeguards will be insisted upon. The remarkable feature of this epidemic has been the occurrence of over 1000 cases without any death directly attributable to the disease.

Contract Practice in New South Wales.

Some time ago the New South Wales Branch of the British Medical Association drew up a model agreement for contract practice, which was declined by the Friendly Societies. A conference between representatives of the medical profession and the societies was subsequently held, and a compromise was attempted. The Friendly Societies' representatives have proved unable to get their concessions ratified, and the situation now shows signs of becoming difficult. The practitioners engaged in contract practice have given in their resignations of all contract appointments, and the Branch Council of the British Medical Association has notified the Friendly Societies, for its members, that unless an agreement is arrived at the resignations will take effect from the end of the present year. Some of the societies are now for fighting the medical profession. Another party are for renewed parleying, with the object of further investigation of differences. Finally, a few "lodge combinations" have frankly accepted the terms asked by the profession.

The foundation by Mr. Wellcome of a museum illustrating every part of the history of medicine is another event of the past year which is likely to have influence on this branch of medical study. Those who visit the museum will often be encouraged to add to it or to make additions to knowledge from that which they have there acquired.

It is just ten years since the first lectures on the history of medicine were delivered at the Royal College of Physicians of London, and the College may justly feel satisfaction in the consideration that its efforts have been crowned by an international approval of the encouragement of the study by the formation of a section in the Congress.

A knowledge of the history of medicine acquired from the writers of each period and from other original sources of history will be of constant use in teaching medicine at the bedside. The errors of the past often show how to avoid error in our own day. The way in which truth was slowly attained in the past often suggests ways of attaining truth in the case under observation. A well-known case from history often helps to impress on the student's mind the facts of a similar case actually before him. These are a few of the uses of history at the bedside.

By a knowledge of the history of his profession and of its work every man gains in dignity, for he comes to live in contact with the men who have added to knowledge in the past as well as with those who increase it in his own time. He is a greater man because he knows so clearly what he owes to Harvey, what to Laennec, and what to Lister, that they become the daily companions of his thoughts. It may be hoped that the study of the history of medicine, which has made so important an advance in 1913, will continue to flourish in this country.

This letter ought not to end without mentioning how great a loss the study has suffered in the death of Dr. Milne—

Dead ere his prime;

His deep learning was displayed at the Congress in his admirable paper on Galen's "Knowledge of Muscular Anatomy."

THE LANCET has, I think, in the past given much encouragement to historical subjects which must be my excuse for writing at such length.

I am, Sir, yours faithfully,

Dec. 29th, 1913. NORMAN MOORE.

A PROPOSED PRIVATE HOSPITAL.

To the Editor of THE LANCET.

SIR,—Little doubt can exist that the accommodation offered to sick people, other than those of the poorer classes, by the existing nursing homes is very bad—that it is very much inferior to that offered in the large public hospitals. This state of things can easily be traced to the failure of an attempt to carry on private hospitals in houses primarily designed for domestic uses, and all the present well-known defects can be traced to that cause. The obvious remedy, therefore, is to build a large central private hospital for paying patients —to establish, in fact, a hotel for sick people in place of the existing lodging-houses. I am writing with particular reference to the needs of London, but have no reason to suppose that those needs are not just as pressing in all large cities.

I am convinced that such an institution must have at least 150 to 200 beds (there are at present over 1000 in the West-end—of course, scattered through medical and surgical homes), that it must be centrally situated in order to be a convenience to both the public and the surgeon, that it must be capable, as to price, of housing all a medical man's cases who can afford fees, and, as far as its accommodation goes, must begin where the modern hotel has left off, not where the hospital has stopped. A person used to the conveniences of a modern hotel does not want less comforts when ill. The matter is one out of which nobody desires to make large profits, and the finance should be arranged so that excess earnings over a certain percentage should go to relieve the fees due from necessitous cases on the less expensive side.

At the moment there are a lot of factors present which should make the effort to establish such an institution successful. I have been working at the subject for some years, but it is one that requires the coöperation of all people interested, as divided or isolated efforts are only likely to lead to failure. Therefore, I shall be pleased to add my endeavour to that of others, and give all the details I have collected to anyone who is disposed to help along the project.

I am, Sir, yours faithfully,

ANTHONY B. BRADFORD, M.D. Durh.

Henrietta-street, Cavendish-square, W., Dec. 22nd, 1913.

BIG GAME AND SLEEPING SICKNESS VERSUS MAN AND HIS ANIMALS.

To the Editor of THE LANCET.

SIR,—In letters on the above subject published in your columns Mr. Sheffield Neave and Dr. G. D. H. Carpenter query the statement of Professor J. L. Todd in his letter to THE LANCET of Nov. 22nd that "The situation is clear; big game, especially antelopes, are the reservoirs of, and Glossina morsitans is the carrier of, trypanosomes which cause fatal disease in man and animals." Both quote Taute's experiments as evidence against the interpretation which Dr. Kinghorn and I have placed upon our experimental findings in Africa—that a large proportion of the wild game harbour trypanosomes pathogenic to man and his animals. May I point out that the single experiment performed by Dr. Taute upon himself proves nothing beyond the fact that it is possible for a healthy human being to resist infection. There is certainly no justification for assuming from a solitary experiment of this kind that the trypanosome found by Kinghorn and myself in game and wild Glossina morsitans is other than the, at present, absolutely indistinguishable parasite known to infect man and domestic stock in Rhodesia and Nyasaland. Taute's observation merely affords an explanation of the fact that so comparatively few human beings are infected in these areas; in other words, that healthy human beings are able to a great extent to resist infection. This fact is not very astonishing when we remember that there is no case on record of man being infected by any of the common pathogenic trypanosomes of domestic stock, such as T. congolense, T. vivax, T. evansi, T. equinum, or T. equiperdum.

If experimental inquiry is to be conducted along these lines then one must insist that the work be carried out on a sufficiently large scale, and generalisations not made from a single experiment. As we have had to deal with what has up to the present proved to be an invariably fatal disease it was some time ago obvious that definite results could hardly be hoped for from experiments on human beings. It is not even permitted to make use of condemned criminals for such purpose.

The onus of proof lies with those who state that the trypanosome found by Dr. Kinghorn and myself in game and wild Glossina morsitans—identical as regards its morphology, pathogenicity, and development in the tsetse with the trypanosome found in man and his domestic animals—is not the human trypanosome. I have repeatedly urged that the only practicable means of obtaining information on this point as on several others, such as the dependence or not on game of Glossina morsitans for its existence and infectivity, is by carrying out the experiment to which Professor Todd refers in his letter.

Many of those who oppose an experiment of this kind being undertaken adopt the almost incomprehensible attitude that it is necessary to be sure beforehand that the hoped for results will certainly be obtained. In effect they say: "First prove that if the game in a certain district be exterminated either the tsetse will disappear or will become noninfective and then we will permit the experiment." If these results could be known beforehand obviously we need not trouble to perform the experiment, but might proceed at once to attack the game in the neighbourhood of human habitations situated in fly areas.

I am, Sir, yours faithfully,

WARRINGTON YORKE.

Runcorn Research Laboratory, Liverpool School of Tropical Medicine, Dec. 16th, 1913.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 29th Mr. Sheffield Neave writes: "Bruce's theory that T. rhodesiense is nothing else than T. brucei must carry great weight." I should like to point out that whatever T. rhodesiense may be, it is certainly not T. brucei. This name was first given in 1899 by Plimmer and Bradford to a trypanosome which was sent to this country from Zululand. This strain of trypanosome is still extant at Runcorn and in several of the European laboratories.

Sir David Bruce, working at a later period in Uganda, found in an ox a trypanosome which he described as T. brucei. As this Uganda trypanosome is quite different from the Zululand one, the rules of nomenclature will not permit of the name T. brucei being applied to it. The Uganda parasite is identical morphologically, and as regards pathogenicity in laboratory animals, with T. pecaudi and T. rhodesiense, so that if the name T. rhodesiense is to be dropped it must be in favour of the name T. pecaudi, which was the first applied to trypanosomes of this type, and not T. brucei. These points were clearly brought out in a recent communication to the Royal Society by Professor J. W. W. Stephens and myself.—I am, Sir, yours faithfully,

B. BLACKLOCK.

Runcorn Research Laboratory, Liverpool School of Tropical Medicine, Dec. 16th, 1913.

A WORD ON THE TREATMENT OF SYPHILIS BY SYRIAN QUACKS.

To the Editor of THE LANCET.

SIR,—Every medical man confesses that the treatment of syphilis by mercury is a long and tedious process. I am inclined to think that many of us fail to cure syphilis quickly, if we cure it at all, because we are so over-cautious as to giving large and effective doses. In the last few months I have had a chance to follow closely the line of treatment that is followed by quacks in this country and I was surprised at the short time in which they "cure" syphilis. Mercury is used in all cases. The patient is kept for the greater part of a week in a room, tightly closed, and is instructed to fumigate calomel and to keep the room at a uniform amount of saturation. The patient is allowed to leave the room for fresh air, but is indoors for the greater part of the time, and also sleeps in. If I am correctly informed by patients who have undergone this treatment, no cases experience more than slight salivation. At the end of a week the patient quits the fumigation treatment and for two other weeks is put on a diet strictly confined to bread and infusion of sarsaparilla—he is allowed to eat nothing else.

In the last two or three months I have seen several patients who have been relieved of their symptoms by no other means than this method, and they were "cured," they said, in about three weeks. Certainly, no symptoms of syphilis could be detected in the cases that I had brought to my attention, some of which had received treatment two or three years previously and since have not felt any symptoms of the disease. Might this not be good testimony, though it comes from unqualified quacks, to the efficacy of large doses of mercury in the treatment of this disease? I do not consider the fumigation method to be of especial value, except in this, that by it the patient gets large quantities of mercury, both through his lungs and through his skin, and he gets it constantly.

I am, Sir, yours faithfully,

K. S. KRIKORIAN.

American School of Medicine, Beirut, Syria.

REFLECTIONS BY A SICK SEPTUAGENARIAN.

To the Editor of THE LANCET.

SIR,—Having been recommended to rest in bed by my medical advisers I have tried to obey orders and I have in a measure carried out their instructions, and yet I confess I have for the first time discovered that *complete* abstinence from exertion implies the steady and continuous services of one nurse at least. So far fortunately I have not, or fancied I have not, required such unremitting attention.

In the course of an active professional life I have now had the first opportunity of perfect leisure, and have been able to indulge in a course of uninterrupted reading. After dosing myself with *belles-lettres*, biography, and fiction, with a little poetry thrown in, I have upon several occasions fallen back on medical current literature, and this is my excuse for troubling you on this occasion. No doubt there are many practitioners who keep themselves *au courant* with the medical literature of the day. On the other hand, there are to my knowledge others too busy—or so they think themselves to be; and these practically do not know what is going on in the larger world of science and practice, and in consequence are falling behind in the race of professional progress. Such a man "takes in" a medical paper or papers, and often does not even remove the cover! I have heard the story of a country doctor, in an interval of spare time, paying a visit to his neighbour. Walking in unannounced, to his dismay he heard a bullet whizzing past his head. To his startled inquiry as to this mode of reception he was told that his warlike friend was practising pistol shooting, his target for the nonce being the back numbers of a highly influential medical journal. To such vile uses may the best of literature be put!

But it is time to come to the point of why I am addressing you, or rather your readers—I wish to impress upon them, or more correctly some of them, how much they lose by not perusing, for example, your pages, and how they should order their lives so as to secure time for such study. Take The Lancet for four consecutive numbers and let me mention a few of the interesting tit-bits to be found in the one month—November. I shall take them at random. The first, and as it happens the best, is Mercier's address on "Heredity," sparkling with humour and full of sound sense, though I think he forgets the apophthegm as to the mothers of men of genius; and next that on "Hysteria" by Glynn, based as all such "prospects" should be on a carefully recorded past experience. The report by Davis and Hall on the intensely interesting question of "Typhoid Carriers," and the not less valuable remarks of Gowland Hopkins on "Diseases due to Deficiencies in Diet." Tubby's suggestive paper on "Nerve Surgery," also Cammidge's on "Diabetes," your review on Davenport's "Eugenics," and the leading article on "Housing in Dublin"—a problem on this side of St. George's Channel, alas! as well as in Ireland. To Insurance panelists the continuation of the valuable local inquiries by your highly capable contributor is enough to make the one week's issue interesting by itself.

Dr. Mott's able paper on the "Degeneration of the Neurone" should make the following number equally so, while Sir Dyce Duckworth's Liverpool address constitutes a timely warning against the adoption of jejune theories as applied in the practice of medicine. The subject of neurasthenia as dealt with in the issue for the last week of the month affords an excellent example of the value of the personal equation both as regards doctor and patient. An unprejudiced study of the combined wisdom of the leading London neurologists amounts merely to this—that not one of them can properly define the subject in debate further than agreeing that the nerve battery is "run down," though in most cases it cannot be said whether the defects have arisen from bad initial construction, from injury, or from failure in the supply of the chemicals required.

And now, to cease to be garrulous and become didactic, I venture to advise my medical brethren to take one forenoon out of the seven in bed, preferably on a Sunday, and post themselves up in the current literature of medicine, surgery, and obstetrics, as also in the pressing professional problems of the day.

I am, Sir, yours faithfully,

Dec. 29th, 1913. William Bruce.

*** Abraham Cowley supplies us with a quotation: "We grieved, we sighed, we wept; we never blushed before."—Ed. L.

THE PREPARATION OF THE MOUTH FOR OPERATIONS.

To the Editor of The Lancet.

Sir,—In reference to the case of cancer of the tongue and larynx removed by operation, and reported by Mr. W. S. Kerr in your issue of Dec. 20th, 1913, some ten years ago I saw in a London hospital nine consecutive cases of major operations about the tongue and floor of the mouth end fatally a few days after the operation. Death in each case was due to septic complications obviously caused by pyorrhœa alveolaris, which at the post-mortem examinations I observed to be present.

Shortly after this, in a further series of five cases, I was called in to prepare the mouth for the operation. This was done by the extraction *of all the teeth and stumps*, followed by antiseptic treatment of the wounds for a week or ten days (painting the surface of the gums with a 2 per cent. solution of iodine in rectified spirit twice daily is probably the best method). These five patients were alive and well three months after the major operation.

In my next case the patient absolutely refused to have all his teeth removed. He would only allow me to extract the loose ones. I carefully scaled and cleansed the remainder. He died about six days after the major operation from septic complications.

My experience since has confirmed me in my belief that if periodontal disease is present *even in a slight degree* the only safe course is *to extract every tooth* at least one week before the major operation. It should be remembered, too, that practically every hospital patient has pyorrhœa.

It is difficult to understand the attitude of the surgeon who takes infinite precautions to sterilise the area of operation before making a skin incision and who yet will perform an extensive operation in the mouth actually in the presence of pus.

I am, Sir, yours faithfully,

F. St. J. Steadman, M.R.C.S. Eng.,
L.R.C.P. Lond., D.P.H.,
Assistant Dental Surgeon to the West London Hospital, &c.
Wimpole-street, Cavendish-square, W., Dec. 20th, 1913.

AMŒBIC DYSENTERY?

To the Editor of The Lancet.

Sir,—The greater part of the medical profession in this country seem to be singularly blind to the possibility of their patients acquiring tropical diseases without going abroad, and yet we are all familiar with the fact that many tropical animals and plants become acclimatised and thrive here; there is nothing incredible, therefore, in the idea that the micro-organisms of tropical diseases may equally thrive in England and reproduce their specific diseases in this temperate climate. The following case may serve for an illustration.

At the end of last August, a man aged 30, consulted me as to diarrhœa, from which he had suffered continuously since childhood, at least 18 years. The stools were putty-coloured and varied between 5 and 15 a day. It had been difficult for him to carry on his business, and he was quite unable to join in social functions. He had during the worst attacks considerable pain and tenesmus, followed by bloody stools for a week at a time. During several years he had been treated by various eminent physicians. The diagnoses varied—"nervous diarrhœa," intestinal tubercle, and disease of the colon (needing operation) were a few out of many. One nasal specialist put the whole trouble down to post-nasal catarrh and wanted to remove part of the turbinated bone. The patient told me of many remedies which had been prescribed with no effect for more than a day or two.

A few months ago I had been discussing with my daughter, who practises in India, tropical dysentery and other intestinal cases. Bearing in mind what I had learned from her, I came to the conclusion that the case before me might be one of amœbic dysentery, and advised the patient to have a course of hypodermic injections of emetine hydrochloride. After a delay of several weeks he agreed; for six consecutive days I gave hypodermically ⅓ gr. of the salt each morning. After the second dose, on Oct. 16th, the stools dropped to one a day, and became normally coloured and formed. When the drug was left off after the six doses the improvement remained, and on only four occasions since has he had more than one evacuation in a day. Three days before the hypodermic injections were begun his weight when stripped was 9 st. 4 lb., now it is 10 st. 1 lb. It seems, therefore, as if a cure has been effected, and that probably the diagnosis was correct. The patient has never been out of Great Britain. My opinion is that the disease was acquired when he was living in Plaistow, Essex, either through contaminated food or water.

If, on the other hand, my diagnosis was wrong, then the treatment seems worth trying in other forms of obstinate diarrhœa, especially in cases where tubercle of the intestine is suspected. As a matter of precaution the patient has had six more hypodermic injections at intervals of three days, though no relapse has occurred. No other medicine has been used since Oct. 16th. The old name given to ipecacuanha by Helvetius, "radix antidysenterica," is more deserved than it ever was, now that the unpleasant effects of the remedy can be eliminated by the use of the alkaloid.

I am, Sir, yours faithfully,
VERE G. WEBB.
Dec. 25th, 1913.

INTESTINAL KINKS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Dec. 20th your correspondent, Mr. C. Hamilton Whiteford, has raised some very pertinent queries regarding the effects of angulation or kinking of the intestines. This subject has received so much attention lately that by many it is looked on almost as a fetish, invoked to explain all disorders, and the present mode in surgery is to introduce a new theory of cause and effect. Without apology, therefore, I conform to the general attitude, but ask leave to plead rather for the utility of peri-visceral adhesions. Abdominal veils and bands, in my opinion, are sometimes noxious, yet in many instances a helpful function may be exercised by their presence. A decade ago one heard that an all-wise Providence had provided the appendix, tonsils, and foreskin as appropriate trophies for the lesser surgeons; nowadays one imagines that the large intestine is the legitimate prey for their maturer years.

Nature does not always work viciously, and one must accept with caution the destructive pessimism of the over-zealous partisans of ileo-sigmoidostomy. Taking Mr. Whiteford's questions seriatim, I believe—

1. A band in itself may produce no symptoms of obstruction, either by angulation or by reducing the calibre of the gut. Normal kinks are found in the human intestine, and Keith has shown that 20 per cent. of fœtuses have aberrant accessory adhesions. How many cases endowed at birth with these present symptoms of stasis in infancy? The band may for a time exercise beneficial control, but afterwards become stretched and lax, allowing enteroptosis to occur, with stagnation of the fluid contents, and this effect is really due to non-efficient support; the useful fixation of the band is lost. It may by condensation and shortening drag upon a coil, pulling it up and causing angulation to such degree that stasis occurs. In some cases misfortune arises from the non-support of portions of intestine, which properly splinted in position by adhesions would not become displaced, while an adjacent part fixed by the band remained in the proper site. Lastly, the band may produce stasis by constriction. Where an adhesion has been present for a time and later shrinks, causing kinking or narrowing of calibre of the gut, I believe this to result from a sclerosis largely the effect of change during middle age, and resembling the hardening got in the connective tissues generally, as in the brain, eye, heart, arteries, or prostate. This I have named "condensation obstruction," a condition which might be avoided were the general youthfulness of the tissues preserved in some way. Note especially how volvulus tends to occur after middle life from shrinking of an adhesion pedicle approximating a loop of intestine at its base.

2. A kink may produce obstruction; on the other hand, a sheath or veil of adhesions may prevent it by preventing over-distension. I have at present in my wards a patient whose great intestine at operation showed a reticulated cicatricial mosaic exactly like the striæ albicantes after pregnancy, and suggesting a similar origin, coming on after alternate contraction and distension of the colon, causing slight tears and cracks which fill up with connective tissue. Such a cicatricial effect would exert centripetal pressure on the intestine, preventing over-distension and thus preventing stasis. This arrangement might be compared to the tartan envelope which encases the national instrument of Scotland, preventing the stasis of its melodies. Also the effect in causing enhanced velocity of the contents is as that in carcinoma of the rectum, where diarrhœa ensues when the natural ballooning is interfered with, and a portion of dilatable intestine is replaced by an immobile tube of solid cancerous tissue. Apart from obstruction or diarrhœa, or neither, a kink or adhesion may produce chronic or recurrent pain in the abdomen.

3. The bowel proximal to a kink may present no change, may be hypertrophied to overcome resistance, or may be dilated. Jordan's plates clearly show the latter effect. In cases of atonic dilatation look to the neuro-muscular regulating apparatus as well as to the muscular coats.

4. The radiographer might decide the question of other symptoms than those of obstruction or dilatation.

5. A kink in a portion of intestine drawn up to or beyond an incision in the abdominal wall is *not* proof that such exists in the passive state. On the other hand, I have seen a case of fatal intestinal paresis with definite kinking without adhesions of any kind causing it, the condition being entirely due to increased intravisceral pressure with sharp angulation at a flexure causing a collapse, much as happens when a goose quill is bent acutely.

I am, Sir, yours faithfully,
SPENCER MORT,
M.D., Ch.B. Glasg., F.R.C.S. Edin.
Edmonton, Dec 23rd, 1913.

IODINE IN THE DRESSING OF WOUNDS.

To the Editor of THE LANCET.

SIR,—I have recently returned from the Balkans after a year's absence. After leaving Adrianople, where I worked for three months, I was invited to join the fourth division of the Bulgarian army, as a medical officer, during the operations against the Greeks and Serbs, and I remained from the outbreak of war to the conclusion of the infamous treaty of Bucharest with the Bulgars.

During this period I saw and treated many fresh wounds by the iodine treatment, and can vouch for its wonderful efficacy. How often, however, does one see wet dabs used to swab out the wound prior to the application of iodine? Mr. H. F. Waterhouse and Mr. W. S. Fenwick have shown that in the preparation of skin by iodine the importance of keeping water away prior to the application is paramount.

Why I am asking you to publish this letter is not so much to recommend the dry treatment of wounds, but, after a really huge trial, to recommend the cleaning of the skin round the wound and even the wound itself with a 1 per cent. solution of iodine in benzene. This is far and away the finest cleansing method I have seen used or have used myself, and I think it was an important factor in the results obtained in the fighting in the Balkan States. I am, Sir, yours faithfully,

Sutton, Surrey. Edward S. Calthrop.

INSTRUCTION IN THE NATURE OF ALCOHOLISM.

To the Editor of The Lancet.

Sir,—Is it not time that the nature of alcoholism and its treatment should be taught more definitely in our medical schools? Whatever he may or may not see in practice, the general practitioner is always bound to meet with these unfortunate victims of alcohol. The question has been brought home to me during the last few years owing to the fact that I see so many patients—victims of pseudo-dipsomania—who have been advised by their medical attendants to limit their drink to a glass at meals—advice which is, of course, absolutely fatal. I do not blame them for a moment. I was never taught anything about alcoholism when I was a student, and I have no reason to suppose things are different now.

May I also call attention to another fatal error, which has, I am sorry to say, the authority of a well-known medical work on its side? Delirium tremens *is* induced by the sudden cutting off of alcohol in the case of a chronic alcoholic after prolonged drinking. It is *not* induced if the drinking bout is only of a few days' duration. Possibly the mistake arose from confusion of the two conditions.

I am, Sir, yours faithfully,
Hugh Wingfield, M.D. Cantab.

Welbeck-street, W., Dec. 17th, 1913.

THE NATIONAL MEDICAL UNION: THE LONDON PANEL.

To the Editor of The Lancet.

Sir,—In The Lancet of Dec. 27th you state that it is reported that the number of practitioners on the London panel in November last was 1458, of whom 88 were resident officers to institutions. You omitted to mention that 100 of these did not reside within the county, and are therefore counted twice over, once in their own county and once in the County of London, thus giving rise to the error that Mr. Lloyd George made when he informed us that the number of doctors on the panel was over 18,000. I am given to understand that the numbers probable are 14,000 panel and 17,000 non-panel. In any case we London men can certainly congratulate ourselves that out of 6300 names on the Medical Register only about 1300 have "eaten" their written words and are now servants of the London Insurance Com mittee. The National Medical Union is the nev non-panel federation. Its members have a higl standard of medical honour, and are men wh would sooner suffer financial loss than lower thei professional dignity.

It is, in my opinion, the duty of all non-pane men to join the union. The secretaries state "tha applications for membership are coming in wit encouraging and continuous volume."

I am, Sir, yours faithfully,
E. H. Worth, M.R.C.S. Eng.

Streatham, S.W., Dec. 27th, 1913.

THE PSYCHOLOGY OF RAILWAY ACCIDENTS.

To the Editor of The Lancet.

Sir,—Your leading article on the above subjec compels attention to a seriously frequent failure c human efficiency in the individual, condoned by hi associates, who obviously do not think they coul do the work better, nor that they should be asked t do it better. Are we, then, as Mr. G. K. Chesterto once asked with bated breath, losing our efficiency Or is it that we do not pay enough heed t our jobs? In the old days when people ha nothing to occupy them but their jobs the were proud of their jobs. Now when we hav got away from work we can read the paper we can go to moving pictures if in town, work on our allotments if in the country; have these other things getting between us and o work, and the boasted skill of the craftsman, t artist's sacrifice of the man to his work, comes longer forward, but one hears rather of successf evasion of duty and of victory over an employer- just the talk one used to hear long ago at schoc but then amongst irresponsible boys. What is be done? I suppose we can only each of us sho a good example of devotion to duty which sha leaven the whole lump, and by the medical profe sion the State will be saved, as Sparta by Tyrtaeu

I am, Sir, yours faithfully,

Victoria, B.C, Canada, Dec. 4th, 1913. W. E. H.

PS.—My best congratulations on your "reversio to type." The change is very acceptable.

A Munificent Bequest.—By the death of Mr. Geoffrey Charles Ansell, which took place recently, a large sum of money has become available for various charities under his father's will. Mr. Ansell, who was only 17 years of age, met with an accident in Switzerland some two years ago. The bequests include £50,000 to King Edward's Hospital Fund; £25.000 each to the National Society for the Prevention of Cruelty to Children and the Royal Society for the Prevention of Cruelty to Animals; £10,000 each to Charing Cross Hospital, Guy's Hospital, *the London Hospital, the Middlesex Hospital,* St. Bartholomew's Hospital, St. George's Hospital, St. Thomas's Hospital, and Westminster Hospital; £4000 each to King's College Hospital, University College Hospital, the Royal Free Hospital, the Great Northern Central Hospital, the Cancer Hospital, Fulham-road, the Brompton Hospital for Consumption and Diseases of the Chest, City of London Hospital for Diseases of the Chest, Royal Hospital for Diseases of the Chest, London Fever Hospital, London Lock Hospital and Rescue Home, National Hospital for Diseases of the Heart, Queen Charlotte's Lying-in Hospital, Royal London Ophthalmic Hospital, Royal Orthopædic Hospital, Hospital for Diseases of the Throat, Nose, and Ear, Royal Hospital for Children and Women, Hospital for Sick Children, Great Ormond-street, and the Victoria Hospital for Children. The ultimate residue of the estate is to be held in trust for London Hospitals.

THE NATIONAL INSURANCE ACT.

WORK OF THE MEDICAL REFEREES.

A REPORT has been presented to the London Insurance Committee with reference to the work of the medical referees lately appointed. About 30 Approved Societies had made use of the scheme, and over 700 applications had been dealt with. The following analysis was given in respect of 471 applications received to the end of October:—

—	Report of medical referee after examination.		Action where no examination was made.		Total.
	Capable.	Incapable.	Cases withdrawn.	Cases in suspense.	
Men	33	54	13	3	103
Women	175	113	63	17	368
Total	208	167	76	20	471

In the 76 cases withdrawn by Approved Societies examinations were arranged, but the insured persons failed to attend. In the majority of such cases they "declared off" from benefit. Of the 208 persons reported as "capable" of work 30 per cent. were originally furnished with certificates for debility, anæmia, weakness, &c., and 15 per cent. with certificates for rheumatism and dyspepsia. The reports did not show that any high percentage of these cases were malingerers, but that low vitality, lack of nourishment, and mental inertia were predisposing causes of "invalidism." The few cases of obvious malingering had generally been in respect of persons in receipt of low wages. The interpretation of "incapable of work" had presented some difficulties, and in some cases the referees had reported that though incapable of his usual work an insured person was capable of light work. The question whether pregnancy in itself should be regarded as incapacity also arose. The need for an extension of the drug tariff, to include such appliances as trusses, elastic stockings, and spectacles, became apparent in many cases. The number of cases in which incapacity was traceable to some extent to defective teeth was remarkable, especially in cases of rheumatism and dyspepsia. Many of the certificates of practitioners appeared to have been questioned because they did not indicate clearly the nature of the illness. Some discussion took place on the report, and it was decided to send a copy of the report to the Departmental Committee on Excessive Sickness Claims, with the proviso that no extension of benefit should take place without adequate financial assistance from the Government. It has been urged that pregnancy should be regarded as entitling to sickness benefit, and that extensions of the drug tariff in special cases should be possible.

NATIONAL MEDICAL UNION.

The Provisional Federating Council of the National Medical Union have formulated the following policy, viz:—

1. To maintain the freedom of the medical profession in its professional and personal relations with the public.
2. To support the public in maintaining a corresponding freedom and to safeguard the national health.
3. To oppose the present arrangements for medical benefits under the National Insurance Acts, and to decline professional service under such arrangements.
4. To preserve an independent attitude with regard to party politics.

They add that this is a preliminary statement only, and is intended to indicate the broad lines upon which the future policy of the Union will be evolved as soon as the present Provisional Federating Council have completed their duties of organisation. New non-panel associations have been formed, and the honorary secretaries of the Union state that many members from all parts of the country have been enrolled.

The Provisional Federating Council say that it is necessary to make it clear that the Union is an organisation pledged solely to non-panel interests. The offices are in the *Morning Post* Buildings, 346, Strand, London, to which address all non-panel practitioners who are in sympathy with the policy outlined are invited to write.

Medical News.

UNIVERSITY OF OXFORD.—The following degrees have been conferred:—

D

B

The following candidates have been approved in the undermentioned examinations:—

Diploma in Public Health.—Part II.: C. H. Browning, R. H. Deans E. T. H. Lea, T. J. Mackie, and H. K. Ward. Part I.: E. G.

F

I

Terry.

Second ... *Medica and Pharmacology.*—

H. E. ... beare, K. M. Dyott, A. G.

East, ... H. Got h, T. E. Micklem,

T. S. ... Jones O. B. Pratt, A. B.

... and H. St. H. Vertue.

... an, J. A. G. Sparrow, and C. W.

... *Health.*—A. C. Ballance, J. D. Batt,

... V. Dennis, R. S. A. Heathcote, G. T.

... Venables, W. W. Waller, and R. O.

Ward.

Medicine, Surgery, and Midwifery.—A. C. Ballance, E. W. Carrington, R. S. A. Heathcote, G. T. Hebert, E. W. N. Hobhouse, A. H. Southam, J. A. G. Sparrow, W. W. Waller, and C. W. Wheeler-Bennett.

UNIVERSITY OF CAMBRIDGE.—The following medical degrees have been conferred:—

... Vick, Jesus.

... F. H. Oliver, Caius.

At examinations held recently the following candidates were successful:—

THIRD EXAMINATION (*Old Regulations*).

... *Midwifery and Medicine.*—W. Prys-Stones, B.A.,

... n, B.A., Down-

... A., Pembroke;

... A., Emmanuel;

... Nangle, Caius;

... M. Postlethwaite, B.A., Emmanuel;

... Sparrow, M.A., and J. W. Stretton,

... B.A., Sidney Sussex; and F. W.

THIRD EXAMINATION (*New Regulations*).

Part I., Surgery and Midwifery.—D. C. G. Ballingall, B.A., Emmanuel; P. H. Berry, B.A., King's; W. G. Bigger, B.A.,

Trinity; ...

Trinity; and A. W. Uloth, B.A., Pembroke.

Part II.—E. J. Bradley, B.A., Jesus; J. Brewer, M.A., Emmanuel; E. H. P. Brunton, B.A., Trinity; E. N. Butler, B.A., Clare; J. Deighton, B.A., Trinity; G. D. East, B.A., Emmanuel; B. O. Ewens, B.A., Caius; A. R. Jennings, M A., Jesus; H H. Mathias, B.A., King's; P. W. Ransom, B.A., Pembroke; A. V. Stocks, B.A., St. John's; A G. G. Thompson, B.A., Pembroke; and R. L. M. Wallis, M.A., Downing.

University of London.—At examinations held recently the following candidates were successful:—

M.D. Examination.

Branch I., Medicine.—Thomas Beaton, Charing Cross Hospital; Wilfred E. Burrows, Middlesex Hospital; Hazel Haward Cuthbert, London (Royal Free Hospital) School of Medicine for Women; Reginald Robert Elworthy, Westminster Hospital; William Charles Fowler, University College Hospital; Geoffrey Hadfield, St. Bartholomew's Hospital; Robert Henry Hatten Jolly, Charing Cross Hospital; Cicely May Peake, London (Royal Free Hospital) School of Medicine for Women; Ernest Edward Andrew T. Rigg, Harry Dudley Rollinson, and Alfred Richard Spencer, University College Hospital; George Edgar Septimus Ward, Middlesex Hospital; and Gordon Reginald Ward, Westminster Hospital.

Branch III., Mental Diseases and Psychology.—Ralph Brown, University College and Westminster Hospitals; and Alfred Alexander Webster Petrie, University of Edinburgh.

Branch IV., Midwifery and Diseases of Women.—David John Harries, University College Hospital; Reginald Larkin, Guy's Hospital; and Arthur Arbuthnot Straton, St. Mary's Hospital.

Branch VI., Tropical Medicine.—Robert Kelsall, Victoria University of Manchester and London School of Tropical Medicine.

M.S. Examination.

Branch I., Surgery.—Harry Cecil Rutherford Darling, University College Hospital; and Ernest Frederick Finch, University of Sheffield.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

Society of Apothecaries of London.—At examinations held in December, 1913, the following candidates passed in the subjects indicated:—

Surgery.—S. de Moor (Section I.), Amsterdam; J. de Silva (Sections I. and II.), St. Mary's Hospital; R. B. F. Frazer (Section II.), Charing Cross Hospital; J. A. Prendergast (Sections I. and II.), Leeds; and D. Schonken (Section I.) and J. D. Schonken (Section I.), Amsterdam.

Medicine.—E. M. D. N. Baker (Sections I. and II.), Brussels; A. C. O. Brown (Sections I. and II.), Birmingham; H. V. Capon (Sections I. and II.), St. Bartholomew's Hospital; J. de Silva (Sections I. and II.), St. Mary's Hospital; and J. E. Taylor (Sections I. and II.), Leeds.

Forensic Medicine.—J. de Silva and G. L. Lawlor, St. Mary's Hospital.

Midwifery.—S. de Moor, Amsterdam; and J. de Silva, St. Mary's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—A. C. O. Brown, H. V. Capon, R. B. F. Frazer, J. de Silva, and J. E. Taylor.

Victoria University of Manchester.—At examinations held in December, 1913, the following candidates satisfied the examiners:—

Final M.B. and Ch.B.

O. R. Allison, Allan Barrett, Ada L. Bentz, W. R. Blore, F. S. Charnock, C. H. Crawshaw, H. N. Crossley, H. S. Gerrard, Cornelius Thompson, F. K. Tomlinson, C. H. Whittall, H. W. F. Williams, G. W. Wood, and W. H. Wood.

Medicine and Obstetrics.—H. C. Duffy.

Forensic Medicine and Toxicology.—J. E. Brooks, *E. A. Linell, W. A. Rogerson, J. R. Slack, *Henry Wilson, and W. H. Wood.

* Awarded distinction.

Third M.B. and Ch.B. Examination.

J. C. Bramwell, J. S. Chorlton, S. G. J. Dowling, *A. T. Gibb, J. D. Kenyon, J. G. McKinley, H. M. von Mengershausen, H. H. Stones, C. G. Todd, *Frank Vause, Louis Walton, and Richard Willan.

* Distinction in Pathology.

Pharmacology, Therapeutics, and Hygiene.—William Halliwell J. F. C. O'Meara, M. C. Paterson, and C. G. Todd.

Second M.B. and Ch.B. Examination.

*J. H. Albinson, J. D. Byrd, Hitchon Chadwick, W. P. Christopher, Richard Colley, E. W. Fish, Eva L. Glasier, Alice M. A. Holt, J. L. Leigh, B. L. Lloyd, R. L. Newell, F. C. Ormerod, J. A. Panton, Nesta H. Perry, Dorothy Potts, Walter Stansfield, Brian Walley, and G. B. Wild.

* Awarded distinction in Anatomy.

First M.B. and B.D.S. (Part III.)

R. J. Allison, G. E. Hayward, Elizabeth C. Powell, and James Yates.

University of Liverpool.—At examinations held recently the following candidates were successful:—

Degrees of M.B. and Ch.B.

Second Examination.—Part A: N. J. Allan, M. Azer, R. Coope, A. J. B. Griffin, Amy Hodgson, Mary E. Illingworth, S. Pool, A. McK. Reid, and E. S. Stubbs. Part B: H. Garas (with distinction), A. G. McColl, L. Oldershaw, H. C. Roberts, and J. Rumjahn.

Final Examination.—Part I.: R. J. Minnitt, J. J. K. Pentony, and R. H. G. Weston. Part II.: H. G. Bywater and F. C. Wilkinson.

Degree of B.D.S.

Third Examination.—A. E. Meeson (with distinction).

Diploma in Dental Surgery.

Third Examination.—R. Baron and B. R. Townend.

Diploma in Tropical Medicine.

C. M. Austin, S. S. Banker, M. Carrasco, J. M. Clark, E. C. Hepper, I. O. K. Khaw, J. C. Noronha, E. O'Connor, A. B. Pestonji, E. A. Smith, S. D. Stewart, E. L. Wilbe, and H. F. Wilson.

University of Leeds.—At a Congregation of the University held recently degrees were conferred as follows:—

Bachelor of Medicine and Bachelor of Surgery.—H. L. Taylor (with second-class honours), L. H. Butler, W. D. A. King, and K. Menon.

The following pass lists are announced:—

Final M.B. and Ch.B.—Part II.: W. H. Lonen. Part I.: H. S. Bhalla, C. M. Gozney, H. S. Lockwood, C. H. Seville, and Jessie Smith.

Second M.B. and Ch.B.—Part II.: S. Adler, H. E. Charles, C. W. Dudley, Emily E. V. Glover, G. F. Hurst, W. O. Lodge, L. Mosses, J. H. Parker, N. Pick, M. Rosenewige, W. O. Rowden, P. Shillito, I. Silverstein, and C. H. Smith. Part I.: Jane Bamford, C. W. Dudley, Z. P. Fernandez, W. L. M. Gabriel, F. H. Goss, C. R. Knowles, I. Liberman, W. O. Lodge, M. Rosenewige, A. L. Telling, and F. Walton.

Diploma in Psychological Medicine.—W. Robinson.

Dental Examinations.

First B.Ch.D.—Part III.: G. R. Baxter.

Final L.D.S.—Part I.: H. V. Waddington and N. T. Williamson.

Foreign University Intelligence.—*Bonn:* Dr. R. O. Neumann, of Giessen, has been appointed t the chair of Hygiene, in succession to Dr. C. Ziegler, who i going to Freiburg, but will not enter upon his new dutie until after the termination of the winter session.—*Breslau* Dr. Josef Forschbach, *privat-docent* of medicine, has bee appointed Chief Physician of the Medical Policlinic.—*Frank fort:* A new municipal hospital for nervous diseases has bee opened at Köppern.—*Greifswald:* Dr. Paul Adloff, chie surgeon to the University Dental Clinic and *privat-docent* c odontology, has been granted the title of Professor.—*Strasburg:* Dr. Oesterle, professor in Berne, has been offere the chair of Pharmaceutical Chemistry, in succession to th late Dr. Schaer. Dr. G. Skeiner has been recognised a *privat-docent* of Psychiatry and Neurology.—*Tokio:* D Aoyama, dean of the Medical Faculty, on the occasion of h twenty-fifth year "jubilee" as a professor, has been electe an honorary member of the German Society of Nature an Social Science.

National Bureau for Promoting the Genera Welfare of the Deaf.—At the second annual meetin of this Bureau, which was held recently at 22, Uppe Brook-street, London, Mr. Leo Bonn, the President, i moving the adoption of the report, said that the yea 1913 had been one of exceptional activity and remarkabl results in all branches of work connected with th deaf, and alluded to the progress made by the Bureau a specially marked by the publication of Dr. J. Kerr Love's lectures on the Causes and Prevention of Deafness. These lectures had, he said, created universal interest, and a medical committee of the Bureau has now drawn up a series of practical proposals for the prevention of deafness, based upon their conclusions which the executive committee is considering. Mr. P. Macleod Yearsley, having said that Dr. Kerr Love had, by his devotion to the cause of the deaf child, raised for himself a monument of which any man might be proud, referred to the practical suggestions for the prevention of deafness, both hereditary and acquired, made by the medical committee of the Bureau, which had sent a deputation to the London County Council to enlist the sympathy of that body. This deputation, he considered, had nothing to complain of in its reception, and if an endeavour to arouse the recently formed Central Health Committee for London to a sense of duty to the deaf had not been quite so successful, that matter would probably come up again. Mr. Yearsley then dealt with the suggestions for the prevention of acquired deafness, especially with the necessity for appointing aural surgeons to fever hospitals, placing school centres for the treatment of ear diseases under specialists, and the notification of meningitis and syphilis, and gave it it as his sincere belief that if these suggestions were given practical form deafness might be made to pass away from amongst us, as Dr. Kerr Love had said, within the next three generations. The fight that was before them was a very strenuous and uphill one, not because there was opposition, but because there was so much apathy. He liked opposition, it strengthened one and could be dealt with like a boulder across the road—it could be moved or blasted away; but apathy was like mud, it clogged and clung, making progress terribly difficult. Mr. B. St. J. Ackers, Mr. F. G. Barnes, and the Rev. F. W. G. Gilby dealt with various aspects of the problems presented by the deaf population, and Dr. C. W. Saleeby moved a vote of thanks to the chairman.

ON Dec. 16th, at Buckingham Palace, Dr. James Forster, of Conisbro, was decorated by the King with the silver life-saving medal of the Order of St. John of Jerusalem for gallantry at the Cadeby mine disaster in 1912.

THE ANTHRAX COMMITTEE. — Sir Thomas Whittaker, M.P., has resigned the chairmanship of this committee, and Mr. W. Middlebrook, M.P., has been appointed chairman in his stead.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART.—The opening ceremony of the new hospital in Westmoreland-street, Marylebone, W., will be performed by H.R.H. Prince Arthur of Connaught, K.G., at 3.15 P.M. on Monday, Jan. 12th.

ROENTGEN SOCIETY.—The secretary asks that members of this society, the next meeting of which takes place on Monday, Jan. 5th, will note that the time and place of the meeting have been altered. The meeting, as advertised in our Diary of medical events, will take place at Middlesex Hospital, W., at 8.15 P.M.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Dec. 18th, 1913, Sir Francis H. Champneys being in the chair. A letter from one of the Board's examiners, asking the Board to reconsider its refusal to approve Mary Robinson for the purpose of training candidates for the Board's examination in practical work was further considered, also a communication from Dr. J. J. Buchan, medical officer of health for Bradford, on the same subject. The Board decided that the application be granted, but that the authorities of the Leeds Maternity Hospital be asked to satisfy themselves that the rules of the Board are being fulfilled with regard to pupils at Bradford, and that for the year 1914 the certificates of pupils at Bradford be countersigned by the authorities at Leeds. A letter was considered from a registered medical practitioner asking for approval to sign *pro hâc vice* an examination certificate on behalf of a candidate in respect of a portion of her cases. The Board decided that the application be granted. A letter was considered from the town clerk of Warrington asking the Board to restore to the roll the name of a woman which had been removed from the roll at her request on the ground of ill-health in 1910. The Board directed that the medical officer of health for Warrington be asked: (*a*) whether the woman in question is able to take temperatures correctly; (*b*) whether she does so in all cases attended by her, according to the rules of the Central Midwives Board; (*c*) whether her register was well kept while she practised as a midwife; and (*d*) what she has been doing since her resignation.—At a special meeting of the Board on Dec. 19th a number of midwives were struck off the roll, the following charges, amongst others, having been brought forward:—Attending confinements for the purpose of assisting an uncertified person who had been struck off the roll of midwives, to continue habitually and for gain to attend women in childbirth in contravention of Section 1 (2) of the Midwives Act; being unable to make use of a clinical thermometer, and consequently unable to take the temperature of patients as required by Rule E. 13; neglect to take the necessary steps to secure the cleanliness and comfort of the patient as required by Rule E. 11, leaving her after the confinement in a very dirty and neglected state, and failing to comply with Rule E. 7 (b); giving a false certificate and a false notification to the local supervising authority that the child was stillborn; a child suffering from inflammation of and discharge from the eyes from the fourth day, and so suffering during the residue of the midwife's attendance she did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 20 (5); not keeping the register of cases as required by Rule E. 23; not habitually taking or recording the pulse or temperature of patients, as required by Rule E. 13; when called to a confinement, not taking the appliances and antiseptics required by Rule E. 2.

A CENTENARIAN.—The death has occurred at Symondsbury, West Dorset, of Mrs. Wilkins, in her 101st year.

SILVER WEDDING GIFTS TO CHARITY.—Mr. Lawrence Cotton and his brother, Mr. Clement Cotton, have each given £1000 to the Blackburn Infirmary for the purpose of endowing cots in celebration of their respective silver weddings.

LITERARY INTELLIGENCE.—Major W. S. Patton, I.M.S., of the King Institute of Preventive Medicine, Guindy, and Captain Francis W. Cragg, I.M.S., of the Central Research Institute, Kasauli, have just issued a textbook on "Medical Entomology," intended to meet the needs of medical, sanitary, and veterinary officers who have to do with diseases communicated to man and domestic animals by means of insects.

ROYAL INSTITUTE OF PUBLIC HEALTH.—A course of instruction for tuberculosis officers, school medical officers, and medical practitioners will be delivered during January, February, and March in the lecture room of the institute, 37, Russell-square, London, W.C., on Fridays at 5 P.M. The particulars will appear in our diary of the week, and further information may be obtained from the secretary, Mr. E. L. Ryley.

A COMPLETE SCHOOL CLINIC.—The council of the county borough of St. Helens, Lancashire, has established a fully equipped school clinic for the treatment of ear, throat, and eye defects, and also minor ailments. An X ray [illegible] l for the treatment of ringworm [illegible] nary tuberculosis. In the same [illegible] om the clinic, is a tuberculosis [illegible] nsulting-, waiting-, and dressing- [illegible] y for the examination of specimens. A sanatorium providing accommodation for about 60 cases of phthisis will be opened in the course of a few weeks.

ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON.—For some time extensive work has been going on at the Royal Sussex County Hospital, Brighton, in the construction of outside balconies, and the work having now been completed the balconies were formally opened on Dec. 17th last, following a special court of the governors. Three of the balconies on the west side have been given by the late Mrs. David Smith, widow of a former Member of Parliament for Brighton; the extension of the Overton ward balconies was provided by Mrs. William Jones, and the whole of the eastern balconies—at the Defflis, Egremont, Peel, and children's wards—were the gift of Miss Louise Sassoon. The president of the institution, Mr. C. R. Scrase Dickins, who declared the balconies open, thanked the donors who had given to the medical and surgical staff the means of helping their [illegible] speed.—At the same go [illegible] spend £4250 on structu [illegible] of the heating and hot water service, by which it is hoped to effect substantial economies.

ROYAL INSTITUTION.—The following are among the lecture arrangements at the Royal Institution before Easter:—Professor W Bateson, Fullerian professor of Physiology, Royal Institution, six lectures on Animals and Plants under Domestication. Dr. W. McDougall, two lectures on the Mind of Savage Man (illustrated by the Pagan Tribes of Borneo): (1) His Intellectual Life; (2) His Moral and Religious Life. Professor C. F. Jenkin, three lectures on Heat and Cold. Dr. C. W. Saleeby, two lectures on the Progress of Eugenics: (1) The First Decade of Modern Eugenics, 1904–14; (2) Eugenics To-day, its Counterfeits, Powers, and Problems. Dr. J. A. Harker, two lectures on the Electric Emissivity of Matter: (1) The Metals; (2) Other Substances (with experimental illustrations). Professor Sir J. J. Thomson, professor of natural philosophy, Royal Insti-

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—Honorary Radiographer, Surgeon Laryngologist, and [illegible]. Also House Physician at Northwood. Salary [illegible] Queen-[illegible]

NORTH KENSINGTON SC[illegible] Officer. Salary £50 per annum.

NOTTINGHAM CHILDREN'S HOSPITAL.—Female House Surgeon for six months. Salary at rate of £100 per annum, with apartments, board, and washing.

NOTTINGHAM GENERAL DISPENSARY.—Resident Surgeon, unmarried. Also Assistant. Salary £220 and £180 per annum respectively, with apartments, &c.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Surgeon. Salary £100 per annum, [illegible]ndry.

NOTTS COUNTY COU[illegible] Sherwood Forest, Mansfield.—Resid[illegible] £100 per annum, with board, residence, and laundry.

PERTH DISTRICT ASYLUM.—Assistant Physician. Salary £150 er annum and all found

PORTSMOUTH, ROYAL PORTSMOUTH HOSPITAL.—Pathologist. Salary £150 per annum.

PRESTON, COUNTY ASYLUM, Whittingham.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, and washing.

ROCHDALE INFIRMARY.—Second House Surgeon, unmarried. Salary £100 per annum, with board, residence, and laundry.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Clinical Assistants in Out-patients' Department.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Assistant Physician.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Junior Resident Medical Officer for six months. Salary at rate of £70 per annum, with residence, board, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Acts at Sowerby Bridge, in the county of York; at Warminster, in the county of Wilts; and at Worthing, in the county of Sussex.

*** The summary of vacant appointments, published weekly in this column, is, equally with other articles, the literary copyright of the Proprietors of THE LANCET.

Births, Marriages, and Deaths.

BIRTHS.

BECK.—On Dec. 21st, 1913, at Bromyard, the wife of Ashton Beck, M.B., of a daughter.

DEANE-BUTCHER.—On Dec. 24th, 1913, at Pittsworth, Queensland, to Dr. C. B. and Mrs. Deane-Butcher, a son.

GUNN.—On Dec. 18th, 1913, at Neston, Cheshire, the wife of George Gunn, M.D., F.R.C.S.E., of a son.

DEATHS.

FLEMING.—On Dec. 22nd, 1913, suddenly, Alexander John Fleming, M.D.

THORNTON.—On Dec. 28th, 1913, at Berkeley Lodge, Trinity-square, Margate, Bertram Thornton, M.R.C.S., L.R.C.P., in his fifty-seventh year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

NOTES ON DIARIES.

A GOOD diary is essential to most people, and especially to medical practitioners, and both Messrs. Cassell and Co. and Messrs. John Walker and Co. provide a wide selection suitable to all tastes and for all purposes. Both firms include with their diaries an insurance coupon for £1000, the coupon being made valid on payment of a small registration fee. So excellent are the productions of these firms that the only difficulty in making a selection is the wide choice which is given to the purchaser. Messrs. Cassell and Co. publish the "Letts's Diaries and Calendars," the sizes varying from two to three inches square up to quarto and foolscap size interleaved scribbling diaries. The bindings are of leather or cloth according to price, which ranges from 6*d.* upwards. They are ruled for one day to a page, two days to a page, seven days to a page, or a week in an opening.

We call special attention to the two following diaries:—

Letts's Medical Diary for 1914, which, in addition to the usual postal and general information and almanacs fo 1913 and 1915 as well as for the current year, contains great deal of matter useful to medical men. The pages o the diary are ruled on the plan of a week to an opening with spaces for patients' names, visits, and ledger folic Ruled pages are provided for accounts and for various pro fessional engagements. The diary can be had in two sizes ruled respectively for 54 or 108 patients, and the pric varies, according to the binding, from 2*s.* 6*d.* to 4*s.* an from 4*s.* to 5*s.* 6*d.* respectively.

Letts's Nurses' Report Book and Diary for 1914 shows i the diary a week to an opening, and contains an almana and general information. There are also double-pag ruled openings with columns for recording the vario duties and observations incidental to nursing. Blan lettered pages are also provided for an index. The pri is 2*s.*, neatly bound in red cloth.

Messrs. John Walker and Co.'s large selection includ their convenient and well-known loose-leaf diaries, made i different sizes, bound in morocco lined with leather, an with or without pockets. These diaries are suitable to a purposes, and will be found particularly useful by medic men and students (prices 2*s.* 9*d.* to 9*s.* 9*d.*). Re-fills can b obtained at a cheap rate. The other diaries issued by thi firm in sizes from 2 inches by 3 inches and upwards, an with one or two days or a week to a page, or a week t an opening, are bound in cloth or leather of varying kind according to the price (9*d.* to 8*s.*).

Both Messrs. Cassell and Co. and Messrs. John Walker and Co. also publish some useful wall calendars.

The Cambridge Pocket Diary, 1913-1914 (London and Cambridge: the University Press), is unique as a diary, inasmuch as it has been arranged for the academical year, and therefore covers in part two calendar years. It is in size suitable for the waistcoat pocket, and contains information of interest to Cambridge men and also to others in academical and legal circles. The price, according to binding, varies from 1*s.* to 2*s.* 6*d.* net

The Cambridge Diary for the Academic Year, 1913-1914, is also issued by the same publishers, price 1*s.*, in block form, each sheet measuring 8 inches by 10 inches. Ample space is afforded for manuscript notes or engagements.

The Wellcome Photographic Exposure Record and Diary, 1914 (Burroughs Wellcome and Co. Pp. 280. Price 1*s.*), besides being a useful diary, forms a concise guide to photography. Both the beginner and the expert will find the contained information, as well as the ingenious exposure calculator included with the book, of great value Three editions of the diary are published: one for the northern hemisphere, one for the southern, and one for the United States of America.

Amateur Gardener's Diary and Dictionary (London: Office of *Garden Life*. Pp. 277. Price 1*s.*) is published in a stiff paper cover, and is a handy calendar and guide for gardeners. It contains, in addition to a useful dictionary of gardening, notes on the weather and the work to be done in the garden and greenhouse during each week of the year.

The Live Stock Journal Almanack, 1914 (London: Vinton and Co., Limited. Pp. 344. Price 1*s.*; cloth 2*s.*), contains besides the diary and breeders' table and the usual general information, articles of interest to stock-raisers, with much information about stock, agricultural societies, fairs,

and a breede
Animals, by Insect Pets
and Live-stoc will be of
interest to veterinary surgeons

Wright's Improved Physicians' and Surgeons' and Consultants' Visiting List, compiled by ROBERT SIMPSON, L R C P, L R.C S. (Bristol: John Wright and Sons, Limited; London · Simpkin, Marshall, and Co), in addition to the
usual postal and
for the visiting
a manner to co
for professional
motor expenses
tables giving such information as the professional man may at times require at a moment's notice The *Visiting List* is bound in leather, with pockets in the covers and a *pencil in the fold of the flap It is issued in two forms*—as
a yearly diary and as a bool
any time and used continua
first form varies from 5s. t
of patients' names it will
second form is published at 5s. 6d.

MARTIAL AND MEDICINE.

To the Editor of THE LANCET.

SIR,—It has for over 15 years been one of my most fascinating amusements to see
the classical authors, both
also from medieval Fren
having interest from a med
of which have at various
scarcely refer, therefore,
Raymond Crawfurd's arti
THE LANCET of Dec. 6th. From Martial I have one not referred to by Dr. Crawfurd. It is I 19:—

Si memini, fuerant tibi quattuor, Aelia, dentes;
Expulit una duos tussis et una duos.
Iam secura potes totis tussire diebus,
Nil istic quod agat tertia tussis habet.

If I remember aright, your teeth were but twice two in number.
Two you spat out in a cough, another cough robbed you of two
Now you may cough all day long with a mind that no fears can encumber,
For surely 'tis clear as can be there is nought for a third cough to do.

I venture also to append renderings of two of the passages quoted by Dr. Crawfurd. The first is of the Epigram to Symmachus (V., 9), and was published five or six years ago in the *Boston Medical and Surgical Journal* —

When, out of sorts, I send an urgent call,
You come forthwith, good Symmachus, with all

Has frozen stiff. And thus it comes at last
That while before no fever I endured,
'Tis of a fever I must now be cured

The second of that to Aulus (VI, 78), published still further back in the *New York Medical Journal*.—

Phryx, good friend Aulus, of one eye had lost
The use, and in the other was dim sighted.
His doctor, Heras, said, "Count well the cost
Of drinking, if you drink, your vision's blighted."
Phryx, smiling, bade his eye a mock farewell,
And ordered flagons deep as quick as winking,
One after one. Shall I the sequel tell?
While Phryx the wine, the wine his sight, was drinking

Finally, as your correspondent Mr. Edwin A. Eade (THE LANCET, Dec. 13th) did not send a translation of the Epigram on Zoilus (II., 16), may I add this?

So Zoilus is sick abed, and with a fever too!
His coverlets have caused it. Were he well
What would his scarlet trappings and his Nile couch find to do?
What story dyes from fragrant Sidon tell?

How could he, save by illness, all his opulence display?
To get well the way is easy to divine—
The doctors cannot help him; let him send them all away
And exchange his gorgeous coverings for mine.

I am, Sir, yours faithfully,
Dec. 30th, 1913. KENNETH W. MILLIGAN.

THE SMALLEST MAN IN THE WORLD.

Mr. John William White, who has been described "as the shortest man in the world," died at Southend on-Sea, Essex, on Dec. 26th, 1913. He was 53 years old, and only 21 inches in height, and was thus shorter than "General" Tom Thumb. A portrait of Mr. White appeared in the *Daily Mirror* of Dec. 29th, and those who wish to make comparisons with Tom Thumb (whose real name was Charles S Stratton, and who is said to have been born at Bridgeport, Connecticut, America, on Jan 11th, 1832) will find a portrait of him and his wife (*née* Warren) in THE LANCET of June 30th, 1900, p 1868 An account of
Tom Thumb's er dwarfs
will be found "Giants
and Dwarfs," Richard
Bentley, New

ASTROLOGY IN MEDICINE.

To the Editor of THE LANCET.

SIR,—I am loth to trespass again on your valuable space, but with your kind permission I wish to express my regret to Dr. Mercier that I misunderstood the following sentences found in the excellent abstract of his lectures given in THE LANCET of Nov 29th (p 1527) —

"It is interesting to carry our minds back with a view to finding how the system originated and how it was maintained. The first was explained by the overwhelming power of authority, the last by the geocentric belief that was overthrown by Copernicus"

I considered, not very unnaturally, that in the last 11 words of that extract it was implied that Copernicus was credited with the overthrow of astrology. Dr Mercier having now declared that he did not call it an argument, I withdraw my

I should lil eply to Dr.
Mercier's sati that I have
always unders s that when
coincidences constantly recur with such regularity and frequency as to remove them from the confines of chance, they prove that the two things which coincide are either cause and effect or the result of a common cause If so, then by observing a long series of coincidences we may be able to discover a natural law 1345 was, I believe, a year of pestilence It may have been that Black Death first appeared in 1346, in Europe, Asia, and Africa—a veritable pandemic. Even so, although it was the year after the occurrence of that rare conjunction of Saturn, Jupiter, and Mars—attended by Neptune—in the sign Aquarius, it should be remembered that Saturn takes about two years and a half to pass through a sign of the zodiac—his period being 29½ years. on the atmo
sphere was still d Vernlam)

Observations
ON
PROPHYLACTIC INOCULATION AGAINST PNEUMOCOCCUS INFECTIONS,
AND ON THE RESULTS WHICH HAVE BEEN ACHIEVED BY IT.[1]

BY SIR ALMROTH E. WRIGHT, M.D., F.R.S.,
IN CONJUNCTION WITH
W. PARRY MORGAN, M.B. CANTAB., L. COLEBROOK, M.B. LOND., AND R. W. DODGSON, M.D. LOND.

(Concluded from p. 10.)

SECTION IV.—*Results Obtained by Therapeutic and Prophylactic Inoculation of Pneumococcus Vaccine.*

WE have now completed the setting forth of the work which we did in connexion with the investigation of the antibacterial effects exerted by the [illegible] ting and [illegible] it. We [illegible] ch were obtained when we passed from laboratory work to actual phylactic and prophylactic inoculation. We may begin with the former.

Treatment of Pneumonia by Vaccine-therapy.

It will be well to realise at the outset under what disabilities of ignorance we here pursued our work. The methods of blood examination which so often disappointed us when we were endeavouring to compare from day to day the opsonic power of the inoculated with that of the uninoculated natives, left us quite in the lurch when we set ourselves to make similar daily measurements in the case of our pneumonia patients. We were unable to trace upon the 50 immunisation curves which we plotted out in connexion with this work the effect of the doses of vaccine which we administered.

Accordingly, from first to last, we had to guide ourselves in our choice of doses and of the intervals between our doses only by *a priori* considerations and by the uncertain and flickering light which is furnished by temperature charts and the clinical symptoms. Influenced by the anticipation that the infected natives would be much more sensitive to pneumococcus vaccine than the uninfected native, we employed only doses of 2½ to 50 millions of pneumococci, and we conformed to the principle of giving in the less serious conditions larger, and in the more serious ones smaller, doses. In the ordinary case we repeated the dose at intervals of 24 to 48 hours.

These experiments—they have only the value of [illegible] patients. Many of these were, when admitted to hospital, already in an advanced stage of pneumonia. We accepted for our experiments only those who presented quite typical physical signs, and these were taken for treatment by vaccine-therapy or for treatment by the expectant method alternately, and strictly in the order in which they were admitted to hospital. We took for every uninoculated patient who was treated by vaccine-therapy an uninoculated control, and for every inoculated patient an inoculated control.

As the net effect of our treatment, we obtained the results which are set out in the subjoined table:—

TABLE XI.—*Showing the Case Mortality of Pneumonia in Tropical Natives treated respectively by Repeated Small Doses of Pneumococcus Vaccine and by Expectant Methods.*

Therapeutic method employed.	Number of cases.	Number of deaths.
Vaccine therapy	159	50
Expectant treatment	149	48

We would in connexion with these results specially emphasise (1) that they apply only to tropical natives who, having a very low power of resistance, have contracted virulent infection; and (2) that they apply only to inoculations carried out on such natives with the doses specified above.

What we have to say in connexion with the prospects of therapeutic inoculation in pneumonia will be better deferred till we come to summarise and comment upon the results obtained by inoculation.

Prophylactic Inoculation against Pneumonia.

We pass now to study the results which were obtained by prophylactic inoculation. The inoculations which we carried out or initiated range themselves under six mass-experiments.

Mass-experiment No. 1.—This mass-experiment was undertaken in the compound of the Witwatersrand Native Labour Association. This compound, familiarly known as the W.N.L.A. Compound, is, as has already been briefly explained, the receiving station at Johannesburg where the gangs of native labourers, who are recruited for the general service of the mines, are housed for three to four weeks before they are drafted off to their respective mines.

We confined our operations in this and the four next mass-experiments to the tropical natives. For it is especially these who are ravaged by pneumonia. In each case, two or three days after the arrival of a new gang, the natives were lined up. We then, dismissing any who showed symptoms of illness inoculated as they filed past us every alternate man, reserving in this way half of each gang to serve as controls. As the men came up to us the inoculated were made to pass on one side, and the uninoculated on the other; and lists were made of the depôt numbers of the two groups—each man's identification docket being at the same time ruled across with a diagonal line, which was red or blue according as he was inoculated or reserved as a control. After the lapse of eight to ten days the natives were again ranged up, and every man who had on the first occasion been inoculated was now reinoculated, while the controls were still kept as controls. The red or blue diagonal line on each man's docket was at the same time converted into a red or blue cross, and a corresponding entry was made upon the lists.

Proceeding in this manner between the months of October, 1911, and April, 1912, with each gang of tropical native labourers as it arrived, we inoculated a total of 5963 and reserved 5671 to serve as controls.

The doses which were employed varied with each gang and subgroup—for we were, as has been indicated above, engaged in following out from day to day the *effect exerted* on the blood by different doses and different schemes of administration. The average amount of vaccine given in the two successive inoculations taken conjointly was something like 300 millions of pneumococci. It in no case exceeded 600 millions.

---

[1] Being Part II. of a Report t[illegible] and 21st (p. 1101), 1912.

The results of the inoculations are furnished, so far as relates to the three or four weeks dating from the first inoculation, in the register of pneumonia cases and deaths kept in the hospital attached to the W.N.L.A. Compound. The clinical diagnosis was in each case made by the medical officer, Dr. George A. Turner, or the assistant medical officer, and by one of us (W. P. M.). In the fatal cases the cause of death was controlled by post-mortem examination carried out by the medical officer.

Information with regard to the subsequent history of the inoculated and uninoculated is furnished in two sets of returns. We have, first, the special monthly returns made to us from the mines—the so-called *red and blue monthly returns*. These record the number of cases of pneumonia and deaths from pneumonia occurring respectively in the red and blue group of tropical natives. We have, secondly, the returns of deaths, and specifically of deaths from pneumonia, rendered thrice monthly from the mines to the Chamber of Mines for the information of Government.

The "red and blue" returns proved unserviceable for our purpose, inasmuch as the depôt numbers of those who contracted, and died from, pneumonia were not supplied, and *also because* the results applying to the separate gangs were not kept apart. The Government returns, since they furnish the depôt numbers of those who succumbed to pneumonia, are those we depend upon for the later results set forth in the table below. The results of the mass-experiment, ascertained as explained above, are as follows:—

TABLE XII.—*Showing the Number of Pneumonia Cases and Deaths from Pneumonia which occurred in the W.N.L.A. Compound between the Date of the First Inoculation and the Departure of the Natives to the Mines.*

—	Number of men in the group.	Cases.		Deaths.	
		Number.	Percentage.	Number.	Percentage.
Inoculated	5963	147	2·6	50	0·83
Uninoculated ...	5671	198	3·5	87	1·53

TABLE XIII.*—*Showing the Number of Deaths from Pneumonia reported from the Mines in each successive Month.*

—	Number of men in the group.	Second month.	Third month.	Fourth month.	Fifth month.	Sixth month.
Inoculated ...	5963	11	19	12	10	7
Uninoculated...	5671	29	19	15	13	8

It will be seen that the inoculation exerted a marked effect for two months, but that after the end of the second month the inoculated had no advantage over the uninoculated.

To obtain the measure of the total effect of inoculation on the death-rate from pneumonia we may combine the figures for the deaths in Tables XII. and XIII.

TABLE XIV.—*Showing the Effect which was exerted upon the Death-rate from Pneumonia in the first Two Months after Inoculation.*

	Number of men in the group.	Deaths.	
		Number.	Percentage.
Inoculated	5963	61	1
Uninoculated ...	5671	116	2

Mass-experiment No. 2.—After Mass-experiment No. 1 had been in progress for a certain time, and after it had appeared from the returns that favourable results were being obtained, we endeavoured to procure larger figures, such as would be really serviceable for statistical purposes, by undertaking "general inoculations" at the mines. We accordingly in December, 1911, and January, 1912, organised and ourselves took part in a number of "general inoculations" at the mines, and Dr. Turner, who helped us in this work, afterwards took independent charge of a number of others. We compute that in all 20,000 to 30,000 natives were in this way inoculated. Our intention was that the inoculated and the controls should, in connexion with these inoculations, have been chosen and registered in exactly the same way as had been done in the W.N.L.A. Compound; and we arranged for a special form of return in which the population of the mines should be divided up into (*a*) inoculated natives, (*b*) natives who were set aside as controls, and (*c*) natives who were excluded from the experiment either because they had joined later, or because they had for other reasons failed to put in an appearance at the inoculation parade. All sorts of difficulties, however, presented themselves in connexion with working out this scheme. It was found very difficult to get the records of the inoculated and controls accurately made when such large bodies of natives as were here in question were being dealt with. Again, the arrangements made for keeping track of the inoculated and uninoculated left in many places very much to be desired. Complications also presented themselves with regard to making proper allowance for natives who left the mines "time-expired" within the period of observation. Lastly, the inoculated turned out to be non-homologous with the controls, and there was—in contrast with what obtained in our other experiments—a sensible defect of homogeneity in the population of natives we were dealing with.

In connexion with the comparability of the inoculated and the controls it may be explained that the native labourers on the Rand come from as far south as the Cape, and from as far north as the Equator; and that there are between the different races of natives at the mines great differences with respect to tractability and susceptibility to pneumonia, the tropical natives being at once the most tractable and the most susceptible to pneumonia, and the East Coast natives, as we are informed, much more difficult to handle and at the same time more resistant to pneumonia. It will be readily understood that under these circumstances the inoculated group would tend to be more largely composed of the more tractable and, as it happens, more *susceptible tropical* natives, and the uninoculated group to be composed of the less tractable and, as it happens, less susceptible East Coast natives.

---

* In compiling this table the fact that the native whose death was recorded in the report from the mines had passed before us, and had been inoculated *or set aside* as a control, was verified by reference to our records; the period which had elapsed since the date of the first inoculation and his death being at the same time ascertained.

In connexion with the homogeneity of the population operated upon, it is to be observed that the fresh arrivals are (as will be seen from the figures for the uninoculated in Tables XII. and XIII., XV. and XVII.) the most susceptible to pneumonia, and that those who have been longer upon the mines have become more resistant to pneumonia. By consequence every group which is chosen from the native population, without reference to length of residence on the mines, will comprise persons of very different degrees of resistance.

As soon as these considerations had, one after the other, come home to us, we decided to bring this particular mass-experiment to a close, and to jettison, as open to fallacy, such statistical returns as had already been sent in to us in connexion with the experiment.

If, as we cannot in view of our other experience doubt, this mass-experiment gave good results, we suggest that the advantage was reaped in the form of a diminution in the general death-rate from pneumonia on the Rand.

Mass-experiment No. 3.—Having learned from experience in Mass-experiment No. 2 the difficulties which have to be confronted and the fallacies which have to be avoided in connexion with a general inoculation, we set ourselves to organise such an experiment upon better lines. The mass-experiment here in question was begun in May, 1912. It consisted in a series of general inoculations undertaken in 20 mines[2] and limited to tropical natives who had, in the season 1911–12, passed out to the mines from the W.N.L.A. Compound. In view of the fact that it had been shown in Mass-experiment No. 1 that there was, after two months, no difference between inoculated and uninoculated, the whole of the tropical natives of the year, with the exception of those few who left the compound for the mines in March and April,[3] were regarded as, for our purposes, homologous.

In each mine three general inoculations were undertaken, approximately a month intervening between the first and the second, and again between the second and the third inoculation; and the dose of vaccine was uniformly 150 million pneumococci. On the *first* occasion approximately half of the tropical natives were inoculated, and half were left as controls—giving a group of 3975 inoculated and a group of 4769 uninoculated. Among these last were counted in a certain number who were actually at work on the mine, but who for one reason or another were not actually forthcoming at the first parade. At the *second* general inoculation, half of those who had on the first occasion served as controls were inoculated; and of those who were on that occasion inoculated one moiety was reinoculated, while inoculation was withheld from the other with a view to find out how long the effect of the previous inoculation would make itself felt. At the *third* general inoculation, again, half of those who functioned at the second inoculation as controls were inoculated, and nearly all those who were previously inoculated were reinoculated.

Quite special care was devoted to ensuring accuracy in the records, the procedure adopted being as follows. For each mine two lists were prepared. On the first (hereafter called the "depôt list") the "depôt numbers," with which the natives leave the W.N.L.A. Compound, were arranged in serial order, the corresponding "mine numbers," which are given to the natives on arrival at their mines, being entered in the second column. On the second list (hereafter called the "mine list") the mine numbers were set down in serial order, and the corresponding depôt numbers were entered in the second column. This done, the depôt list was taken in hand by us, and we inserted in the third column, opposite the numbers, alternately a red or a blue diagonal line—the red line to indicate that the native was to be inoculated, the blue that he was to serve as a control. Corresponding entries were then made on the mine list.

When visiting the mine for the purpose of the general inoculation the natives were identified by their mine numbers as they passed up from their work, and they were inoculated or sent on uninoculated, according as their numbers were marked in red or blue, and the diagonal lines on the list were at the same time converted into crosses to show that these natives had been dealt with. Corresponding crosses were afterwards made upon the depôt list. The returns were made monthly by the medical officers of the mines on printed forms specially issued for this purpose. The return gave in connexion with each patient admitted to hospital his depôt number, the date of his admission, the diagnosis, and the date of his discharge or death.

In Table XV. we have grouped the results under the headings of results in the *first*, *second*, *third*, and *fourth* months. We have included in the results obtained by inoculation in the first month, not only the results which refer to the 3975 inoculated in the first general inoculation, but also the figures which refer to the natives who were inoculated for the first time at the second and third general inoculations. Moreover, in the case where a man was inoculated more than once we have set down in the "results obtained in the first month after inoculation" those which apply to him for the month following each of his several inoculations. For we find by analysis of the figures that the inoculation of men who have been inoculated one month previously with 150 millions gives neither better nor worse results than are obtained where men are inoculated for the first time.

We have dealt in a precisely similar fashion with the results which apply to the uninoculated. For instance, when, in making up our results for the first month, we come upon a man who was at each of three successive general inoculations taken as a control, we enter him in our statistics three times over (once for each several month) in order that he may serve as a control for the men who were inoculated at the first, second, and third inoculations respectively. Similarly, when we come upon a man who was inoculated for the first time at the third general inoculation, we include him twice over in our controls. And when we come upon a man who was inoculated for the first time at the second general inoculation, we include him once in our controls. We follow, *mutatis mutandis*, precisely the same procedure when dealing with the returns which apply to the second, third, and fourth months.

It will be seen that with the very small dose of vaccine which here came into application a very striking advantage was achieved in the first month after inoculation, but that advantage had nearly passed away by the end of the third month. The records are not continued beyond the fourth month because the mass-experiment next on our list was then begun.

---

[2] The mines chosen for the experiment were those which had received the largest number of tropical natives.

[3] These were excluded from the experiment and left out of the record.

TABLE XV.—*Showing Results for Four Successive Months after Inoculation.*

—	Number of men in the group.*	Cases of pneumonia.		Deaths from pneumonia.	
		Number.	Percentage.	Number.	Percentage.
Results for the First Month.					
Inoculated	10,626	125	1·1	22	0·21
Uninoculated ...	10,503	216	2·05	40	0·38
Results for the Second Month.					
Inoculated	6,787	76	1·12	15	0·22
Uninoculated ...	8,380	123	1·5	25	0·3
Results for the Third Month.					
Inoculated	6,103	59	0·96	13	0·21
Uninoculated ...	7,823	92	1·2	22	0·28
Results for the Fourth Month.					
Inoculated	6,103	44	0·72	16	0 26
Uninoculated ...	7,823	68	0·87	20	0·25

* In view of the fact that the corrections which would be applicable under the heading of deaths and repatriations would be quite insignificant, we have not troubled to deduct them from the numbers of the inoculated and uninoculated.

Mass-experiment No. 4.—This experiment consisted in a general inoculation carried out in November in 18 out of the 20 mines which were in question in the last experiment. It relates to those tropical natives who belonged to gangs which passed through the W.N.L.A. Compound in 1912, and who were accordingly due to remain in the mines till at least the end of January, 1913. Those who had in the last experiment served as controls were retained as such, and the rest were reinoculated—in each case with a dose of 1000 millions of pneumococci, grown in part on serum broth and in part on glucose serum broth. In this way there was obtained a group of 610 uninoculated, which for the purpose of such comparisons as those we are here making was undesirably small, and a group of 2322 inoculated. The results as ascertained from the returns rendered on the printed forms referred to in connexion with the last experiment were as follows:—

TABLE XVI.—*Setting Forth the Result Obtained for the Period of Five Months after the Date of the Inoculation.*

—	Number of men in the group.	Cases of pneumonia.		Deaths from pneumonia.	
		Number.	Percentage.	Number.	Percentage.
Inoculated	2322	70	3·0	20	0 86
Uninoculated ...	610	21	3·4	8	1·3

The question as to why larger advantage was not here reaped from inoculation is reserved for discussion in our summary of results.

Mass-experiment No. 5.—This experiment was undertaken upon the tropical natives who arrived in the compound of the W.N.L.A. between the middle of August and the end of November, 1912. The chief objects that it had in view were: (*a*) the determination of the optimum dose of pneumococcus vaccine for prophylactic uses, and (*b*) the decision of the question whether cultivations on glucose serum broth furnished a better vaccine than cultures on the ordinary serum broth. The inoculations were carried out exactly as in the case of Mass-experiment No. 1, with the difference that only every fifth native was taken as a control. The procedure adopted with regard to dosage was to take for the general inoculation in each case doses which had been previously ascertained to be perfectly safe, and then to reconnoitre by inoculating a small group with larger doses.* Advancing in this manner we obtained for study a series of six groups.

The general results may be summarised as follows: Employing a *vaccine prepared by cultivating the pneumococcus on blood broth* and a dose of 250 millions, we obtain, for a period of one month after inoculation, a reduction of the incidence from 7 per cent. in the controls to 3·7 per cent. in the inoculated; and a reduction of the death-rate from 2·9 per cent. in the controls to 1·5 per cent. in the inoculated, that is to say, in each case a reduction equivalent to about 50 per cent. With a dose of 500 millions of the same vaccine we obtain, for the first three months after inoculation, a reduction of about 25 per cent. in the incidence and nearly 50 per cent. of the death-rate. With 1250 millions of the same vaccine we obtain a much less favourable result: a reduction, on a period of three months, of 30 per cent. in the incidence and of only 20 per cent. in the death-rate. We may presume that the dose here employed was too large. Employing *a vaccine prepared by cultivating a pneumococcus on glucose blood broth* we obtain, for a period of two months, with a dose of 500 millions a reduction of 50 per cent. in the incidence and of 40 per cent. in the death-rate. With a dose of 1000 millions we obtain,

---

* We found in these experiments that doses up to 40,000 millions of pneumococci produced nothing more than a very slight constitutional disturbance and a very small rise of temperature. This is in good accord with the generalisation (*vide supra* Section II.) that what counts in the case of an inoculation is not the actual quantum of vaccine we incorporate, but the quantum of antigen set free from it in the organism of the patient.

† It is to be observed that the results of those inoculated with reconnoitring doses are excluded from consideration, and that the uninoculated who serve for controlling the effect of one dose are often the self-same individuals as serve for the controlling of another dose.

over a period of three months, a reduction of 30 per cent. in the incidence and of over 60 per cent. in the *death-rate.* *With a dose of 2500 millions* we again obtain less satisfactory results; a reduction of just over 20 per cent. in the incidence, and a reduction of 35 per cent. in the death-rate.

There can be extracted from the statistical data which are available in connexion with this mass-experiment, not only conclusions bearing on the question of the relative efficacy of the various doses of vaccine which were administered, but also valuable information bearing on the question of the production of a negative phase—information which has, as we shall see, an important bearing on the question of the utilisation of vaccine in the treatment of pneumonia. The data which seem to us important from this point of view are set out below in the form of a table.

The facts which are set forth in this table are, as will be seen, very remarkable. Associating together the figures which apply to Groups A, B, D, and E; *i.e., the groups which received doses up* to 1000 millions of pneumococci, we find that, in the first four days after inoculation, 2500 inoculated had an incidence-rate of 0'52 per cent., and a death-rate in connexion with these cases of 0'16 per cent., while 750[4] controls had an incidence-rate of 1'4 per cent., and a death-rate in connexion with these cases of 0'84 per cent. In other words, the uninoculated had an incidence-rate nearly three times and a death-rate five times greater than the inoculated.

TABLE XVIII.

—	Number in group.	Number of cases of pneumonia which developed.													
		First day.		Second day.		Third day.		Fourth day.		Fifth day.		Sixth day.		First six days.	
		Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.
Group A (inoculated with 250 millions)	646	—	—	—	—	1	1	2	1	—	—	—	—	3	2
Control group	626	1	1	4	1	3	1	2	2	—	—	2	2	12	7
Group B (inoculated with 500 millions)	759	—	—	2	—	1	1	—	—	3	1	1	—	7	2
Control group	764	1	1	5	2	3	1	2	2	—	—	2	2	13	8
Group C (inoculated with 1250 millions)	1582	8	4	2	—	1	1	1	—		—	—	—	12	5
Control group	791	1	1	2	2	—	—	-	—	—	—	1	—	4	3
Group D (inoculated with 500 millions glucose vaccine) ...	463	1	1	—	—	1	—	—		—	—	—	—	2	1
Control group	457	1	1	3	1	3	1	1	1	—	—	2	2	10	6
Group E (inoculated with 1000 millions glucose vaccine) ...	650	—	—	1	—	2	—	2	—	-	—	1		6	—
Control group	595	1	1	4	2	3	1	1	1	—	—	2	2	11	7
Group F (inoculated with 2500 millions glucose vaccine) ...	1582	7	3	11	2	1	1	3	—	2	2	—	—	24	8
Control group	791	1	1	2	2	—	—	—	—	—	—	1	—	4	3

Again, associating together the figures which relate to Groups C and F—groups which received doses of over 1000 millions of pneumococci—we find that 3200 inoculated had for the same period an incidence-rate of 1'1 per cent., and a death-rate in connexion with these of 0'32 per cent., while 800 controls had an incidence-rate of 0'4 per cent., and a death-rate also of 0'4 per cent.

Two important conclusions follow: the *first* is that pneumococcus inoculation undertaken with doses up to 1000 millions had a marked effect in aborting pneumonia and in diminishing the case mortality. Or we may phrase it otherwise. Vaccine therapy as applied to the treatment of pneumonia is successful when doses of 250 to 1000 millions are given in the incubation stage of the disease. The *second* conclusion is that inoculation undertaken with doses of over 1000 millions of pneumococci may perhaps temporarily increase the incidence-rate of pneumonia.

It is perhaps of interest to point out that these conclusions are essentially the same as those formulated in connexion with plague vaccine by Mr. Haffkine, immediately after he had carried out his first mass-experiment in the Byculla Jail, Bombay, in 1898. In that experiment, as in the mass-experiment we are here dealing with, a decisive difference in favour of the inoculated half of the population manifested itself already within 24 hours. And the view that Mr. Haffkine maintained (in contravention to that held by one of us) that plague vaccine does not produce a negative phase, and that it has the power of *aborting* an incipient attack, was afterwards established by evidence accumulated by Miss Alice Corthorn, M.D.,[5] and Surgeon-General W. B. Bannermann, I.M.S.[6] In connexion with this all that requires to be said is that the generalisations in Section II. of this Report —generalisations which have been reached only after years of further work—have made it intelligible that a negative phase should manifest itself with large doses of typhoid vaccine, a vaccine which is easily broken down in the normal organism, and again with all vaccines after the organism has, by foregoing immunising response, acquired bacterioclastic power, and that this phase should make *default in the uninfected organism, and in the early* stages of infection when vaccines, such as plague vaccine and pneumococcus vaccine which are with difficulty broken down in the body, are inoculated.

In concluding this account of the results obtained in Mass-experiment No. 5 we may profitably advert to one more general consideration. It is, as will presently be brought out more fully in Section V., reasonable to expect that an effective inoculation will give an additional bonus in the form of a diminution in the morbidity which comes upon the record under the heading of "Other Diseases." In point of fact, the *records which relate to the particular* mass-experiment we are here discussing show such a reduction. We have our bonus in the form of a 15 per cent. reduction in the "other diseases" of the inoculated, the figures being: *inoculated*, 6224; *uninoculated*, 1545. Cases of sickness other than pneumonia: in *inoculated*, 2154; in *uninoculated*, 620.

We now pass to our sixth and last mass-experiment.

Mass-experiment No. 6.—This mass-experiment was undertaken upon the natives employed in the Premier Diamond Mine—a mine which, despite the fact that it employs no tropical labour, has always suffered very severely from pneumonia. We began with a general inoculation on Jan. 21st, 1912, inoculating at a sitting about 4000 natives. The experiment thus begun was followed up by a methodical inoculation of the recruits who joined the mine. These inoculations were very admirably organised, carried out, and recorded by Dr. J. C. A. Rigby, who was very ably assisted by Mr. H. P. Sheridan. From Jan. 21st onwards till March 15th, 1912, every second native was inoculated as he arrived at the mine. From that date onwards only every third man was kept as a control, and gradually as it became more and more evident that good results were being obtained an increased proportion of the recruits were inoculated.

---

[4] This figure is arrived at by taking the actual number of men who served as controls for Groups A, B, D, and E.

[5] Brit. Med. Jour., Jan. 25th, 1902.

[6] Ibid., Sept. 14th, 1901.

At the outset the dose which was employed was 200 million pneumococci, and gradually as it became clear from the results that were coming in from Mass-experiment No. 5 that the employment of larger doses was indicated the doses were gradually increased to 250 million, then to 500 million, until finally a dose of 1000 million was reached.

Returns which were very carefully prepared were furnished to us every month, and we were further, at the end of the first six months, and again at the end of the first year of the experiment, furnished with a detailed synopsis of the results. These returns are our authority for the facts set forth below.

TABLE XIX.—*Showing the Results for the Whole Native Population of the Mine for the Year beginning Jan. 22nd, 1912, and ending Jan. 21st, 1913.*

—	Daily average strength of the group.	Cases of pneumonia.		Deaths from pneumonia.	
		Number.	Percentage.	Number.	Percentage.
Inoculated	9909	508	5·13	154	1·55
Uninoculated ...	4520	467	10 33	145	3 21

We subjoin also, for reasons that will presently appear, another statistical record which excludes all those who were on the mine on Jan. 21st, 1912, and takes into account all the natives who came to work on the mine during the next 12 months. It may be remarked that the fact that the native at this mine usually works on a six months' contract would make the daily average population equivalent to about half the number of the natives who join in the year.

TABLE XX.—*Showing for the period Jan. 22nd, 1912, to Jan. 22nd, 1913, the Results for the Natives who came in that year to work on the Mine.*

—	Number of natives who joined the mine.	Cases of pneumonia.		Deaths from pneumonia.	
		Number.	Percentage.	Number.	Percentage.
Inoculated	17,431	376	2·16	120	0·7
Uninoculated ...	6,771	348	5·14	120	1·77

Finally, in connexion with the mass-experiment here in question, we may give the figures for the corresponding period relating to the incidence and death-rate of "other diseases" in the inoculated and uninoculated sections of the population. These figures are as follows: *Inoculated*, average daily strength, 9909; incidence rate, 47·2 per cent.; death-rate, 0·93 per cent. *Uninoculated*, average daily strength, 4520; incidence rate, 106·6 per cent.; death-rate, 1·90 per cent.

SECTION V.—*General Survey of the Results obtained by Therapeutic and Prophylactic Inoculation of Pneumococcus Vaccine; and Critical Comment.*

Vaccine-therapy of Pneumonia.

In connexion with the vaccine-therapy of pneumonia we have, on the one hand, the fact that inoculation in the form of small doses frequently repeated was absolutely ineffective (Table XI.); and, on the other hand, the fact that inoculation in the form of a single large dose, administered in the incubation period, often arrested the disease and averted death (Table XVIII.).

That the difference of dose determined the difference of event is to us as good as certain. Let us—recalling to mind the general propositions formulated in Section II.—here take note of the fact that the doses which we found inoperative were doses from which there could, at best, have been expected that they should elicit a local immunising response. Further, let us note that the evocation of such response would be dependent upon a sufficiency of antigen passing into solution in the lymph at the seat of inoculation.

Lastly, let us note that it is quite likely that microbes which are ingested by phagocytes may, from the point of view of the immunising reaction, be left quite out of regard.[7] In connexion with this it is almost superfluous to point out that when comparatively small numbers of microbes are inoculated, and when they come into contact with a lymph which possesses opsonic power, but only inappreciable bacterioclastic power, they will almost certainly sooner or later be ingested by phagocytes.

In general contrast with all this would be what would happen when a large dose of vaccine is inoculated. In this case the microbes would be carried on into the main lymphatic current or blood-stream, with the result that inevitably some would escape phagocytosis, and inevitably some of these would, even if the blood had but very little bacterioclastic power, be broken down. And there would supervene upon the convection of the antigen to the tissues through the blood a systemic immunising response.

As we see no reason to suppose that the conditions appreciably alter, and as we know that the bacterioclastic power of the blood does not sensibly increase when pneumonia develops, we think it reasonable to expect that the favourable results which were obtained by the inoculation of doses of 250 to 1000 millions of pneumococci would repeat themselves if this treatment were applied in the early stages of pneumonia. We were prevented from undertaking a therapeutic mass-experiment upon these lines in the season 1912–13 by the fact that we were then engaged upon Mass-experiment No. 5 (that which furnished the data we have here been reviewing), and had to be on our guard against falsifying the results it was giving by any therapeutic interference.

---

[7] We hark back here to an objection which was long ago (as we think inappositely, because the blood fluids exert a bacteriolytic effect on the cholera vibrio) brought forward by Metchnikoff in connexion with Ferran and Haffkine's anti-cholera inoculations.

Prophylactic Inoculation against Pneumonia.

The comparative statistics which have been set forth above testify, as has been seen, in every case to a reduction in the incidence-rate and death-rate of pneumonia in the inoculated.

In adjudicating upon a procedure of prophylactic inoculation the following general theses must be taken into account.

1. The advantage derivable from a prophylactic inoculation will be limited by the patient's power of immunising response. In accordance with this, one would not expect to achieve as much by inoculation in a naturally non-resistant population—such as that represented by the tropical native labourers on the Rand—as in a more resistant population—such as is, by common repute, represented by the native labourers on the Premier Mine. We may, perhaps, bring into relation with this consideration the fact that we have, as the result of the application of prophylactic inoculation to the tropical natives on the Rand, in *Mass-experiment No. 1* (*Tables XII. and XIII.*) a reduction of 37·5 per cent. in the death-rate of the inoculated upon an observation-period of six months; in *Mass-experiment No.* 3 (*Table XV.*) a reduction of 31 per cent. in the death-rate of the inoculated upon an observation-period of four months; and in *Mass-experiment No.* 5 (*Table XVII., Group E*) a maximum reduction of 50 per cent. in the death-rate of the inoculated upon an observation-period of six months; while we have upon the Premier Mine (*Mass-experiment No.* 6, *Table XX.*) upon a 12 months' observation-period a reduction of 60 per cent. in the death-rate for the inoculated.

2. The advantage derivable from prophylactic inoculation will depend upon the degree to which the population to which it is to be applied has already run the gauntlet of the particular microbic infection in question. In accordance with this, one would expect greater advantage from inoculation when applied to a population newly arrived in the field of infection, than from inoculation applied to a population which had been long in such a field *continuously* exposed. It falls in with this, that while we have in the inoculated in Mass-experiment No. 5, Group E—an experiment in which the uninoculated had an incidence-rate of 15 per cent., and a death-rate of 5 per cent. over a five-month period—a reduction of 35 per cent. in the incidence and of 55 per cent. in the deaths; we have in the inoculated in Mass-experiment No. 4 [8]—an experiment in which the uninoculated had an incidence-rate of 3·4 per cent. and a death-rate of 1·3 per cent. for the same period—a reduction of only 10 per cent. in the incidence-rate and of 34 per cent. in the death-rate. We may further note that we have, in connexion with Mass-experiment No. 6, in the case of the inoculated a reduction in the incidence-rate of 50 per cent., or 58 per cent., and a reduction in the death-rate of 52 per cent., or 61 per cent., according as we take as our controls (as in Table XIX.) the population already on the mine, or (as in Table XX.) the population of new arrivals.

3. Where in comparative statistics we find that the difference between the inoculated and the uninoculated is after a certain time effaced, this does not necessarily indicate that the immunity of the inoculated is diminishing. We may be witnessing, instead of a descent of the inoculated to the level of the uninoculated, an ascent of the uninoculated to the level of the inoculated. This is, presumably, the true interpretation of the fact that our inoculated natives displayed only for a comparatively short period an advantage over the uninoculated. For we have uniformly, in all our records (Mass-experiments Nos. 1, 3, and 5; Tables XII. and XIII., XV., and XVII.), and *therefore presumably independently* of any change in the external conditions—instead of a progressive falling off in the incidence-rate and death-rate of pneumonia in the inoculated, a progressive improvement in the incidence and death-rate in the uninoculated.

The point of interest which here suggests itself is the question as to how the ascent of the uninoculated to a higher level of immunity, and the accompanying progressive improvement in the figures for the inoculated, which is a feature of all the statistics, is to be accounted for. Two alternative hypotheses here suggest themselves. The attainment of a higher level of immunity may be explained by supposing that the most susceptible individuals have been weeded out by death from each group. But this is not a very acceptable hypothesis, for it is hard to believe that infection can ever be distributed over a population in so uniform a manner as punctually to pick out and kill all the more susceptible individuals. It is much more probable that the progressively increasing resistance in both the inoculated and uninoculated groups is achieved by processes of self-immunisation consequent upon minor infections which affect practically the whole mass of the population. We have what we think presumptive proof that such agencies are at work in the fact, already adverted to above, that there were, in practically every group of four to six uninoculated natives whom we employed as controls, some who were almost certainly suffering from minor pneumococcus infections. Not only does this theory furnish, as it seems to us, a satisfactory explanation of the progressive improvement in the figures for both inoculated and uninoculated, but it puts into our hands, as we think, a clue which may guide us in our search for the optimum dose of a vaccine for prophylactic use. In the case where we institute a comparative experiment—and we have the results of such a comparative experiment set out in Table XVII., Groups A and E—*employing in* one group (let us call it *Group No. 1*) *a smaller*, and in another group (let us call it *Group No. 2*) *a larger dose;* and where we then find that in *Group No. 1* the figures, taken when those *for the uninoculated become equally* good, are inferior to those afterwards reached; and that in *Group No. 2* the figures, taken again when those for the uninoculated become equally good, are not afterwards improved upon—we may legitimately infer that in *Group No. 1* prophylactic inoculation left something undone which was afterwards achieved by self-immunisation; and that in *Group No. 2* prophylactic inoculation accomplished, so far as appears, all that self-immunisation was capable of achieving. It will be realised that this amounts to saying that the optimum dose, or series of doses, of vaccine is that which produces an immunising response which is incapable of any further reinforcement; and that we ought to aim at effecting by prophylactic inoculation all that living in the presence of infection, and having actual dealings with infection, is capable of achieving.

4. Comparative statistics furnish only a very incomplete account of the profit earned by any successful prophylactic inoculation. It has among

---

[8] In this mass-experiment the dose of vaccine employed was the same as that in Mass-experiment No. 5, Group E, and the culture medium employed in making the vaccine was also largely the same.

statisticians been too much the habit to give credit only for the profit shown upon comparative statistics, and to disallow credit for maintained advantage unless proof is produced that the incidence and death-rates of the disease have been, as the ordinary statistician would wish, maintained in the uninoculated section of the population. Examples of this method of auditing profits are furnished by the fact that when, in connexion with small-pox vaccination, the statistical records for France, which is very incompletely, and Germany, which is very completely vaccinated, are contrasted; or when, in connexion with typhoid inoculation, the condition in the army in India before typhoid inoculation is contrasted with its condition to-day, when the large bulk of the British troops are inoculated; or when, in connexion with that same process, a comparison is made between the statistics for the Jacksonville Camp in the Spanish-American War, where out of a strength of nearly 11,000 United States troops, all being uninoculated, at least 1729 contracted typhoid, and the statistics for the San Antonio Camp on the infected Mexican frontier, where nearly 13,000 United States troops, who were all inoculated, were massed with only one case of typhoid[9]; the comparison is in each case disallowed on the ground that there were not sufficient uninoculated controls interspersed among the inoculated, or that the contrasted populations were not quite homologous, or that the conditions to which they were exposed were not exactly alike. The statistical auditor who refuses to give any credit upon vouchers which have been left in some point incomplete is, of course, keeping himself well within the law. But he is leaving quite out of regard the equities.

When the question as to how we should evaluate the results of an effective inoculation process (and we may here deal specifically with pneumococcus inoculation) is regarded from this point of view—in other words, when we take a broad view of the probabilities—it will become clear that it would be altogether proper to claim credit:—*in connexion with the inoculated:* (*a*) for any diminished incidence and any diminished death-rate from pneumonia which is attested by comparative statistics for inoculated and uninoculated; (*b*) for any diminished incidence and death-rate from other pneumococcic infections (whether diagnosed as such, or undiagnosed) which come upon the record; and (*c*) for any diminished incidence and death-rate from infections which were not due to the pneumococcus, but were directly consequent upon pneumococcic infection. Further, *in connexion with the uninoculated* section of the community, credit may equitably be claimed (*d*) for any diminution in the incidence-rate and the case-mortality of pneumococcic infections—for the former because a reduction in the number of pneumococcic cases in the inoculated would diminish the general volume of infection; for the latter, because a reduction in the virulence of the infection might reasonably be expected from the diminished "passaging" (i.e., transference from case to case) of the infective microbe.

It is to be noted that it is only the establishment of the general principle that we may anticipate profits under each of these headings, and that these profits cannot equitably be left out of account, which is here vital. The matter of real concern connexion with any effective inoculation procedu is that by it we are transported out of a vicio circle—a *circulus vitiosus* of infection and nc resistance, into a "propitious circle"—a *circul felix* of increased resistance and diminished inf tion. In comparison with the establishment this, it is a small matter that, when fairly enter upon a propitious circle, it becomes impossible tell how much of the sum-total of effects is due inoculation and how much to other causes.

With these preliminary explanations and reserv we may here subjoin a further table which has ref ence to the mass-experiment on the Premier Min

Table XXI.—*Showing for the Whole Native Pop lation of the Premier Mine the Incidence a Death-rate for Pneumonia; the Incidence a Death-rate for "Other Diseases"; and also t Number of Working Days Lost through Illnes for the Months February to May,* in 1911, 191 and 1913 respectively.*

—	1911	1912	1913
Population (daily average strength)	10,426	12,549	15,284
Proportion of the population inoculated	0	About 50 per cent.	About 92 per cen
Incidence-rate of pneumonia	4 per cent.	1·28 per cent.†	0·74 per cen
Death-rate from pneumonia	0·97 per cent.	0·31 per cent.	0·14 per ce
Incidence-rate of other diseases ...	31 per cent.	20·7 per cent.	14·4 per c
Death-rate from other diseases ...	0·51 per cent.	0·38 per cent.	0·34 per ce
Number of working days lost per 100 native labourers	275	177	131

* We have been furnished with data for this comparison only up May, 1913.

† In 1912 the incidence-rate was 0·86 per cent. for the inoculated a 1·7 per cent. for the uninoculated. In 1913 it was 0 6 per cent. for th inoculated and 3 per cent. for the controls.

Section VI.—*Concluding Considerations and R commendations with Regard to the Measures t be taken to Combat the Pneumonia on the Rand*

In considering what measures ought to be taken to combat the pneumonia on the Rand it is essential to start with a proper appreciation of the character and natural history of the disease. The s facts in connexion with the pneumonia which affects the native labourers on the Rand are as follows:—

The disease is—as investigation, and in pa ticular the investigation made by Dr. Turner in Tropical Africa, has shown—unknown, or pract cally unknown, in the native kraals. The disea has no special relation to the mining work on Rand. It takes no heavier toll of the natives work in the deep-level mines of the Rand than those employed on the Premier Mines on op workings. Moreover, the disease is seen at its worst in the compound of the W.N.L.A. among newly arrived natives who have not yet begun the work on the mines. Again, the prevalence of pne monia and other pneumococcic infections a the natives in the mines of the Transvaal can ha no special relation to its climate or to its elevati above the sea level; for these infections caused very heavy mortality among the African nati working upon the Panama Canal at sea level. they also cause very serious loss of life am the negro labourers and soldiers in Rhodesia, t French African Colonies, the Egyptian Soudan, elsewhere. Finally, we have the very material fact, which has been brought out in this report, that the blood of the African native is, so far as relates to its power of phagocytosing and killing the pneumococcus, very inferior to that of the European, and that the capacity for immunising response is also much less in the African than in the European.

---

[9] Russell: United States Army Medical Department, Bulletin No. 2, January, 1913, p. 11.

These considerations make it practically certain that the prevalence of pneumonia on the Rand is to be ascribed to the bringing together into close contact in compounds of a population which has, as a racial character, a low resisting power to the pneumococcus. If this is so, it is obviously a circumstance which ought to dictate our plan of attack, and to determine in particular what place in our scheme of operations ought to be taken respectively (*a*) by measures which aim at preventing the convection of pneumonia from man to man; (*b*) by measures which aim at holding off influences which might impair the natives' resistance to infection; and (*c*) by measures which aim at increasing the natives' resistance to infection.

(*a*) Under the heading of "measures for avoiding the convection of infection from man to man" would come: measures for the earliest possible detection and isolation of cases of pneumonia; measures for the disinfection of the sleeping quarters from which such cases have been removed; measures for diluting the infective matter in these sleeping quarters by schemes of ventilation; and lastly, measures for the quarantining of recovered pneumonic patients with a view to the prevention of a spread of infection from these. With regard to these, we may remark that, while we see no reason to doubt that each of these measures would in its degree counteract the spread of infection, we have grave doubts as to whether they could ever be made effective measures for combating pneumonia on the Rand. We are taking into consideration here, *first*, the fact that it would be a very difficult thing to carry out upon the Rand measures for the early detection and subsequent quarantining of pneumonic cases; *secondly*, the fact that we have on the Rand not only to deal with pneumonia, but also with very numerous cases of lighter forms of pneumococcic infection; and, *thirdly*, the fact that the pneumococcus lives saprophytically on the mucous membrane of a majority of healthy men. Moreover, in connexion with the question of the adoption of measures for preventing the spread of pneumonic infection from man to man, it will be well never to leave out of sight the fact that given a population which, like a European population, possess a relatively high resistance to the pneumococcus, all such measures can be dispensed with.

(*b*) Coming now to "measures for holding off influences which might impair the native normal resistance to infection"—and we have in view here such a measure as the provision of "change houses"[10] for safeguarding the native against chills—we are of opinion that the place of such measures in a plan of campaign against pneumonia is at best a very subordinate one. In this connexion we would again emphasise that the really predisposing moment in the case of pneumonia is to be found, not in those incidental and temporary impairments of resisting power which may occur in connexion with mining work, but in that abiding defect of resisting power which is normal to the native. We have here clearly a fact which dictates recourse to inoculation, and which indicates that a very important place in our scheme of operations ought to be assigned to this measure.

(*c*) Our recommendations in connexion with inoculation are as follows:—

We recommend that prophylactic inoculation should, except only in the case where a mass-experiment is being undertaken, be applied as a routine measure to every native on recruitment. In the light of the results furnished by Mass-experiment No. 5 (Table XVII.), we suggest that a dose of 1000 millions of pneumococci cultivated upon glucose blood broth might appropriately be employed as the ordinary prophylactic dose.

We further recommend that the natives should be reinoculated after the expiration of four months, and that here again a dose of 1000 millions of pneumococci should be employed.

We would not for the present advise any general application of therapeutic inoculation. We would, however, urgently recommend that it should be made the subject of further investigation.

We regard the continued prosecution of research in connexion with inoculation as essential to the attainment of the best results.

We recommend that such research should comprise, on the one hand, the institution of properly controlled mass-experiments, and, on the other hand, the systematic measurement of the protective substances produced in response to inoculation. In such measurements we suggest that the method for measuring the phagocyto-bactericidal power of the blood which is described in this report, or some modification of that method, should be utilised.

In connexion with prophylactic inoculation, the task of research should be to obtain confirmation of the conclusion that we have in 1000 millions the optimum dose for prophylactic purposes. It would also be well to make certain that reinoculation after a period of four months is really required.

In connexion with therapeutic inoculation, the first task of research should, we think, be to institute a mass-experiment in which one large dose of vaccine should be given to the patient at the outset of his pneumonia attack. We suggest that a dose of 500 millions might be tentatively employed in such an experiment, and we think that in such an experiment every alternate patient should be taken for a control.

In concluding this report we desire again to express our obligations to Dr. G. A. Turner for unwearying assistance in connexion with the inoculations which we carried out on the Rand, and to Dr. F. C. Lister, Dr. A. R. Friel, and Mr. G. Friel for valuable help in our laboratory work. We desire also to thank Mr. P. Ross Frames, chairman of the Research Committee and managing director of the Premier Mine, for the helpful assistance he afforded us in both of these capacities. And to Dr. J. C. A. Rigby and to Mr. H. P. Sheridan we owe a very special debt of thanks for their eminently successful achievement—the mass-experiment carried out on the Premier Mine.

Finally, the author of this report desires to express to Dr. W. Parry Morgan, who took independent charge of the inoculation work after March, 1912, his grateful acknowledgments for his initiative and forethought in planning Mass-experiments Nos. 3, 4, and 5, and for the solicitude with which he carried these out. In connexion with our work acknowledgments are also due to the excellent and conscientious labours of Mr. O. Slawkowsky, our chief laboratory assistant, and of Mr. P. Hardwick, our statistical clerk.

---

[10] It may be explained that "change-houses" are sheds in which the native is compelled to change clothes before he emerges from the mine into the open air.

UNPOLISHED RICE AND THE PREVENTION OF BERI-BERI.

BY HENRY FRASER, M.D. ABERD.,
DIRECTOR, INSTITUTE FOR MEDICAL RESEARCH, KUALA LUMPUR, FEDERATED MALAY STATES;
AND
A. T. STANTON, M.D. TOR.,
BACTERIOLOGIST, INSTITUTE FOR MEDICAL RESEARCH, KUALA LUMPUR.

SINCE the publication of our completed report on the etiology of beri-beri in 1911 communications have been published by several investigators who have sought to isolate from rice polishings the substance or substances which are of value in the prevention of beri-beri.

We found that by the extraction of polishings with acidulated alcohol a preparation was obtained which was effective in preventing the occurrence of polyneuritis in fowls fed on polished rice and also in curing that disease. It is to extracts prepared by this method or similar ones (for an effective extract can also be prepared by means of acidulated water) that physiological chemists have devoted their efforts.

In this field of investigation much work has been done by Funk, who tested the various substances which he isolated on pigeons suffering from polyneuritis induced by the consumption of polished rice. To a curative substance prepared by him he assigned the name "vitamine," and gave it a formula calculated from the results of one analysis; this formula he subsequently amended. As the molecular weights are unknown, and as, in the case of complex substances, from the results of a combustion, several formulæ can usually be worked out, it is obvious that the formulæ cannot be accepted without question. Moreover, by the variety of formulæ he has given it is suggested that the substances were impure, and but for the fact that he has reduced the volume of the material in which the active substance or substances are contained, a proprietary name might quite as reasonably have been applied to the curative fraction isolated by us from rice polishings and known to be a mixture of substances. Indeed, Tsuzuki has applied the name "antiberiberin" to the moist, black, sticky residue obtained on evaporation of the alcoholic extract.

Reasonable allowance must be made for the magnitude and difficulties of the task confronting physiological chemists, but it appears that the methods employed in the work need to be improved; those now in use are crude, and are sources of errors because of the incomplete separations they effect, and because of the decomposition they so constantly produce. It may well be that the substance or substances which prevent beri-beri are elusive bodies and may never be isolated in a state of purity, but these problems in no way concern the physician or administrator whose work deals with the prevention and cure of beri-beri.

The fact that the continuous consumption of polished rice as the staple of diet gives rise to beri-beri in man rests on quite other testimony than that derived from experiments on fowls and pigeons, and the fact is equally well established that when rice-eaters substitute unpolished rice for polished rice the disease does not occur.

Further valuable confirmatory evidence has recently been obtained from the results of the expedition conducted by Mr. A. F. R. Wollaston and Mr. Kloss into the interior of Dutch New Guinea, where they had as their objective the exploration of the Snow Mountains.

The task which confronted them was, as both of them well knew, a formidable and an arduous one. Previous experience had shown them that the occurrence of beri-beri meant failure. Thus the Goodfellow expedition of 1909–1911, undertaken to explore the Snow Mountains, was decimated by disease; and Mr. Wollaston, the medical officer to that expedition, has recorded that "in the six months from the beginning of June to the end of November, 39 men showed definite signs of beri-beri and 7 deaths were directly attributable to this cause." The staple of diet was polished rice. A similar fate had befallen all previously recorded expeditions into this country save the one conducted by Moszkowski, in which unpolished rice was used, but as his expedition numbered only 10 men the results were inconclusive.

Convinced therefore that the work of the expedition could not be accomplished if their camp-followers and guard were fed on polished rice, Mr. Wollaston and Mr. Kloss decided that only unpolished rice should be used.

Here another difficulty confronted them. The only kind of unpolished rice which can be purchased in the Malay Peninsula in the open market is that known as parboiled rice. To this kind of rice the natives of India who immigrate to this country are accustomed, and by them it is preferred. It has, however, an objectionable odou and appearance; irritating properties have been ascribed to it, and it has even been thought to predispose to dysentery and the like diseases. Parboiled rice can be prepared free from objectionable properties, but the manufacturers will not s prepare it, and abundant practical experience has shown that the use of parboiled rice is not the solution of the problem of beri-beri prevention.

Braddon held that parboiled rice was a preventive of beri-beri because it had been "cured," and that white rice was harmful because of some poisonous substance contained in it. The excellent results obtained by the use of parboiled rice in the Government institutions of Malaya confirmed the accuracy of his view that such rice was a preventive of beri-beri, but when it was proved that white rice was harmful because in the process of polishing the subpericarpal layers were removed and that parboiled rice was only a variety of unpolished rice, the problem was entirely altered and the prevention of beri-beri was established on a rational basis.

Chinese, Malays, Javanese, and other rice-eating natives may, when deprived of their liberty in prison, be compelled to partake of parboiled rice, but on regaining their liberty they will not continue its use. If, on the other hand, an ordinary unpolished rice or "kampong" rice were in use in such places, a demand would be created for that rice, which would then become available commercially. In this way some real progress might be recorded towards the eradication of a preventable disease.

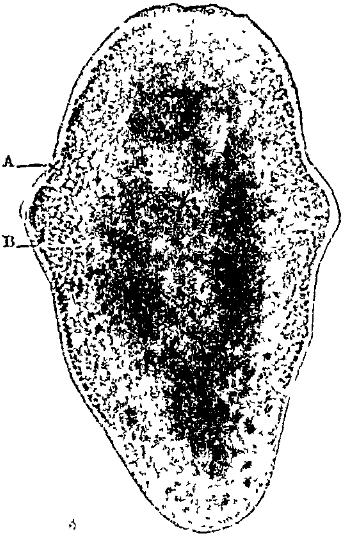
Fortunately, in Java, where the use of parboiled rice is unknown, Mr. Wollaston and Mr. Kloss were able to obtain a supply of unpolished rice adequate for the needs of their expedition. In addition acting on the suggestion of the writers, they took with them as an additional safeguard a supply of a remedial agent, the use of which we have advocated in the prevention and cure of beri-beri.

The expedition consisted of 204 natives of the Malayan Archipelago, who were rice-eaters, with

2 Europeans and 4 Eurasians. They left Batavia about the end of August, 1912, and reached Dutch New Guinea in the middle of September. After reaching the coast the explorers constructed canoes and ascended the Utakwa river. They went as far as possible by water, the journey occupying two days. They then proceeded overland by stages, each stage occupying three days. Camps had to be constructed at each stage, an undertaking of considerable magnitude and one which occupied much time. Four and a half months after they had arrived at the coast they reached the Snow Mountains and then commenced their return journey to the coast, which was reached in two months.

The expedition was in all of seven months' duration, and despite the laborious nature of the work among the 204 rice-eating natives no single case of beri-beri occurred. The general health conditions of the expedition are reported to have been excellent.

The daily ration issued to the natives was as follows: rice, 700 grm.; fish or meat on alternate days, 150 grm.; kachang idju, 200 grm.; Javanese sugar, 50 grm.; coffee, 20 grm.; tea, 5 grm.; salt occasionally, 20 grm. No fresh fish or meat was available during the expedition, only salt fish and meat preserved in syrup.



Transverse section of a grain selected from the rice used on Wollaston Kloss Expedition. A, Pericarp (valueless). B, Subpericarpal zone, the removal of which in the process of polishing converts a harmless rice into a harmful one.

Two varieties of unpolished rice were used. One with a red pericarp was employed during the first five months and one with a silvery pericarp was employed during the last two months. Neither rice could be considered satisfactory from the cosmetic standpoint. In the case of the red variety only a partial removal of the pericarp had been effected, and in the case of the silvery variety no attempt had been made to remove this valueless layer of the grain. Despite the appearance no objections were raised by the natives to these rices, but we think that steps ought to be taken to induce manufacturers to remove the pericarp and thereby improve the appearance of the grain.

In this connexion attention must again be directed to the valueless character of this structure. In previous reports the evidence has been furnished on which this statement is based, but writers, with but one or two notable exceptions, refer to the pericarp as the structure whose removal makes the rice harmful, whereas it is the removal of the subpericarpal layers which is attended by this undesirable result.

The photograph of a transverse section of selected grain (see illustration), which was prepared by the method described on a previous occasion, shows clearly the position of these structures. No real progress in the application of preventive measures can be made until there is available commercially an unpolished rice from which the pericarp has been removed.

Samples of both the rices used were analysed here, with the following results:—

	Red variety.		Silvery variety.
Protein	9·22 per cent.	....	9·41 per cent.
Fat	1·14 "	....	2·10 "
Carbohydrate	78·64 "	....	76·57 "
Ash	1·06 "	....	1·50 "
Moisture	9·94 "	....	10·42 "
P_2O_5	0·54 per cent.	....	0·79 per cent.

It has been consistently advocated that a rice which yields not less than 0·4 per cent. of phosphorus pentoxide may safely be regarded as a harmless one. Both these rices are considerably over this standard, but only in the red variety did any of the grains show a partial removal of the subpericarpal layers, and in the silvery variety the grain had only been deprived of its husk.

Had the enterprise of manufacturers been so far stimulated that removal of the pericarp and embryos from these grains had been effected, the results would have been equally satisfactory as regards the prevention of disease, the analysis would still have yielded results in accordance with the standard of safety, and the cosmetic appearance of the foodstuff would have been greatly improved.

Based on the standards previously adopted the ration was ample, and the scientific findings are thus in complete accordance with the actual facts. The results of this expedition as regards beri-beri are in striking contrast with those which obtained in all previous large expeditions into Dutch New Guinea, and taken in conjunction with the observations and experiments previously recorded the absence of beri-beri on this occasion can only be explained in one way—that is, the absence of polished rice from the diet.

In 1909 we demonstrated: 1. That beri-beri as it exists in the Malay Peninsula is caused by the continuous consumption, as the staple of diet, of rice from which all or the greater part of the subpericarpal layers had been removed by the process of polishing. 2. That a satisfactory measure of the degree of polishing to which a rice had been subjected is the estimation of its total phosphrus in terms of phosphorus pentoxide. 3. That a rice which yields less than 0·4 per cent. of phosphorus pentoxide cannot safely be permitted to form the staple of a diet in man. The further evidence now adduced is in complete confirmation of the accuracy of these statements.

Writers from Southern Nigeria and Brazil have recently disputed the accuracy of these conclusions, but we are unaware that any systematic observations have been carried out in these countries which would permit of a definite statement being made. When these are made it will be necessary to determine that the disease known in these countries as beri-beri is the same as the disease which is known by that name here. After all, beri-beri is only a form of polyneuritis, and students of this disease know that not only forms of polyneuritis of different origin have been called beri-beri, but that even diseases of which polyneuritis may not be a prominent feature, such as "epidemic dropsy," "Ceylon beri-beri," and the like, have been included under this name.

We have shown the mode of operation of the factors concerned in the etiology of beri-beri as it occurs in the Malay Peninsula. The painstaking researches of Highet and his colleagues have proved that the disease is of similar origin in Siam; and the work of Strong and Crowell has furnished similar evidence for the Philippine Islands. In regard to the Netherlands India these results are in complete accordance with those obtained by the very able Dutch investigators, Eijkman, Grijns, and Vordermann, who were pioneers in this field of research.

There is then in the countries mentioned an endemic and epidemic disease which presents certain clinical features, and is known to clinicians in these countries as beri-beri. For the occurrence of that disease the explanation has been discovered. *The disease can be prevented*, and, as we have shown elsewhere, may be cured. But, remembering the old adage that "prevention is better than cure," it is necessary to consider the practical application of preventive measures.

While fully appreciating the work of the scientists who seek to advance our knowledge on this subject, we must attend to the practical issues—namely, the reduction, if not abolition, of the heavy mortality which is yearly exacted by this disease. The determination of exact knowledge is arrived at by processes of abstraction and elimination. In the practical application of that knowledge the disturbing factors have to be reincluded, and it is undoubtedly the difficulty of this task in connexion with beri-beri which has delayed the application of preventive measures. But we are unable to convince ourselves that the difficulties are insurmountable. Political and commercial interests have too long been allowed to control the situation, and though such interests cannot be ignored they should not be given undue prominence. Resolutions on the subject have been passed at all three meetings of the Far Eastern Association of Tropical Medicine, and a resolution in almost identical terms was passed at the recent International Congress of Medicine. These pious expressions of opinion by learned societies have been, and are likely to be, without effect.

We have advocated the preparation of an unpolished rice—*that is, a rice from* which the husk and the pericarp have been removed, and which shall yield not less than 0·4 per cent. of phosphorus pentoxide. At Highet's suggestion such a rice has been produced in Siam, but in the absence of a demand for it, its preparation was not continued. The Governments of the countries concerned can create such a demand by making its use compulsory in all gaols and public institutions. In the Malay Peninsula that form of unpolished rice known as parboiled rice is used in practically all such places, but the use of that rice cannot be extended among the people, and an unobjectionable palatable unpolished rice must be substituted.

A clause in Government contracts, requiring the delivery of an unpolished rice conforming to tl standard, would give opportunity for observing ho such a standard worked in practice and would a in popularising a safe and wholesome foodsti among the people. No one believes that the intr duction of such a measure would be accompani by the immediate disappearance of beri-beri, but is the only way in which progress in its preventi seems possible, and it brings such prevention with the sphere of practical politics.

STUDIES ON GROWTH: THE INFLUENC OF DIET ON GROWTH, NORMAL AND MALIGNANT.

BY CASIMIR FUNK.

(From the Department of Chemical Physiology, Can Hospital Research Institute, London.)

THE idea of influencing the growth of tumours diet is not a new one. Jensen[1] pointed out in 1! that the diet plays an important rôle in the grov *of tumours, and especially in the formation* metastases. Haaland[2] has found that mice kept a diet consisting of cotton seeds, bread, oats, a milk were less resistant to an inoculated sarcoı than mice kept on a restricted diet of bread a oats. These results were corroborated a extended by Stahr,[3] Moreschi,[4] and Medigrecean Rous[5] has observed that mice kept on a diet of oa and rye-flour, maize, milk, and sugar in a quanti just sufficient to sustain life show a differeı behaviour when they are inoculated with tumou before or during this restricted diet. In th first case on animals with large tumours n effect could be noted; in the second case the growt of the tumour was slightly inhibited. These papers however, dealt with the influence of diet as a suppl of nutriment in general. Ehrlich's atreptic theor expounded in 1906 the interesting view that tumour require a specific food-supply. Thus[7] he consider that the reason why a mouse tumour fails to grov for any length of time in a rat is due to a lack of specific food-supply. The important work o Osborne and Mendel,[8] Hopkins,[9] and recentl McCollum and Davis,[10] has taught us to regard the growth, besides being due to a supply of nutritive constituents in general, *as due to a specific "growth* substance." Early in 1913 I pointed out[11] that these results, together with the gain in our know ledge as regards the vitamines, new important con stituents of our normal dietary, cannot fail to produce some effect on the investigation of cancer, and described experiments in this new direction.

Since then two references in the literature deal ing experimentally with the same subject can be found. The first paper is by Sweet, Corson-White, and Saxon,[12] who have described some experiments on mice and rats on normal diet and such devoid of vitamine. The latter diet had undoubtedly an inhibiting effect in the case of mice, where the percentage of takings was decidedly smaller, the incubation period longer, and the tumours smaller than in the case of normal diet. On the contrary, when rats were used very little effect was noted. The second part of this interesting work seems, unfortunately, to contradict the above-mentioned results. The second paper was by Hopkins,[13] which corroborates the results of the American authors. In his cases also the inhibition of the tumour growth was not a complete one. We see from these experiments that it is possible to inhibit the growth of tumours to a small extent, and a question arises whether this could not be applied for therapeutic purposes. We must state here from the beginning that this is as yet hardly possible, and the reasons for these conclusions will be discussed in this experimental paper.

I have recently found that the diet used for the inhibition of growth, which consists of caseinogen, starch, sugar, fat, and salts, produces in pigeons typical beri-beri,[14] and therefore must be regarded as devoid in vitamines. A similar diet can be obtained by using polished rice or a food sterilised in autoclaves at a high temperature. We know, however, that such a diet would unavoidably produce in man in the first case beri-beri, in the second case scurvy.

Showing the arrest of growth in a chicken fed on red (unpolished) rice. Age of chicken, 2 months.

Lately[15] I succeeded in arresting the normal growth of young chickens for the first time on a diet containing vitamines—namely, on red (unpolished) rice, a statement which will be corroborated in this paper. Here was a new hope for influencing the tumour growth without danger of producing a deficiency disease. I therefore inoculated the chickens arrested in growth with Rous's sarcoma, a very virulent chicken tumour which takes in nearly 100 per cent. The result was that the tumour grew undoubtedly more slowly, and was smaller in size than in controls on normal diet. The chickens died sooner than those not inoculated, although no metastases were found, which are very frequent in Rous's sarcoma, an observation which might, perhaps, suggest a greater avidity of the tumour for the food than that of the normal tissues. It seems, therefore, that the growth of tumours and the normal growth of young animals are, although to some extent analogous, not quite identical. The tumour seems to have a much more active metabolism, its avidity for food is greater than that of a normal tissue. These experiments must be considered as a series of orientation experiments in an endeavour to influence the tumour growth by diet. At the present time they do not admit of a practical application, but they suggest that, especially in cases of a quickly growing but not very malignant tumour, such a diet might have some slight inhibitory effect on the rate of tumour growth without producing a deficiency disease.

This work is being continued on broad lines to ascertain the influence of the various constituents of food on tissue growth.

Experiments.

In my first communication[15] on the same subject I have described some experiments on 14-day-old chickens (Plymouth rocks) in which I have arrested growth completely by means of an exclusive diet of red (unpolished) rice. The longest time it was possible to keep alive these stunted chickens was two months. A photograph (see figure) illustrates very well the size of such chickens compared with that of those on normal food. The addition of white bread to the red rice had no effect on the growth of the chickens. I hope to be able to keep the chickens with arrested growth alive for longer periods by a slight addition of some foodstuff to the diet.

Experiment I.—In my first communication the results of tumour inoculation in chickens with arrested growth were not recorded. In this experiment 84 chickens were used, which were divided into seven batches—namely:—

1. 12 chickens on red rice.
2. 12 " " " " *Inoculated after 33 days of the diet with Rous's chicken sarcoma.*
3. 12 " " " " With addition of the same sarcoma extract to the food.
4. 12 " " " " Addition of sarcoma extract, and inoculated after 33 days of this diet with the tumour.
5. 12 " " " " Addition of yeast to the diet, and inoculated after 33 days.
6. 10 " " Spratt's chicken food.
7. 9 " " " " " Inoculated after 33 days.

The result of the inoculation will be seen in the next table:—

Number of batch.	Number of chickens alive at the time of inoculation.	Number of birds bearing tumours.	Diameter of tumour.
2	5	1	¼ cm.
4	5	2	¼ cm.
5	7	5	1 cm.
7	9	8	3-7 cm.

In all these cases except the last no metastases were observed. From this experiment we see very clearly the effect of the addition of Rous's sarcoma and yeast to the diet of red rice, and the fact that no metastases were found must be especially emphasised.

Experiment II.—For this experiment 67 14-day old chickens (Plymouth rocks) were taken, the initial weight of which was 60 grm., in contrast to the previous experiment, in which 80 grm. was the average. They were bred late in the season, and were much more delicate and more difficult to keep alive. The chickens were divided into four batches, one of which was inoculated with the chicken sarcoma on the ninth day of the diet, instead of the thirty-third as in the previous experiment, a time in which the stock of vitamines from the food previous to the experiment could hardly have been completely used up, a fact which accounts largely for the results obtained. The results of the second experiment are summarised in the following table:—

	Not inoculated.		Inoculated.	
Days.	Number of chickens living.	Average weight.	Number of chickens living.	Average weight.
0	24	58 grm.	24	60 grm.
4	24	59 ,,	24	62 ,,
8	24	50 ,,	24	58 ,,
12	17	53 ,,	20	52 ,,
16	11	67 ,,	4	53 ,,
20	10	60 ,,	3	57 ,,
24	5	66 ,,	2	50 ,,

In all the inoculated chickens a tumour developed, except in 4 which died early. This shows that a diet consisting of red rice for nine days previous to inoculation does not prevent the tumour taking, and the growth of the tumours does not influence the growth of the chicken. But the post-mortem examination has shown that the tumour was in all cases, except two where it reached the size of 1½ cm., extremely small, and measured only ½ cm. on the average. Here, as in the previous experiment, no metastases were observed. The death-rate of the chickens inoculated between 3–8 days was a very great contrast compared with the controls.

In another two batches the influence of the addition of phospho-tungstic filtrates from rice polishings and yeast and the influence of the isolated yeast vitamine was also studied with a view to ascertain in which fraction of these foodstuffs the growth vitamine is to be found. The results are recorded in the next table:—

Number of chickens.	Days of experiment.	Average weight.	Nature of addition.	Number of chickens.	Days of experiment.	Average weight.	Nature of addition.
9	0	58 grm.	PWS-filtr., yeast.	10	0	58 grm.	Phospho-tungstic acid filtrate from rice polishings.
9	4	56 ,,	,,	10	4	58 ,,	
9	8	59 ,,	,,	10	8	59 ,,	
9	12	55 ,,	,,	10	12	53 ,,	
9	16	55 ,,	Vitamine 2·5 mgr. daily.	8	16	58 ,,	
8	20	57 ,,	—	8	20	61 ,,	
4	42	65 ,,	—	5	24	60 ,,	

In this experiment the addition of the phospho-tungstic acid filtrates was given instead of water and the vitamine injected intramuscularly. The result obtained shows that the phospho-tungstic filtrate fraction from foodstuffs is not likely to contain the growth vitamine, and suggests that the latter substance is likely to be chemically different from the beri-beri vitamine. A slight effect was, however, observed as regards the time that one was able to keep the young birds alive.

Experiment III.—The next experiment was performed with the view to determine the influence of vitamine-free diet on the growth of Rous's sarcoma in chicken. As vitamine-free di polished rice was chosen; the inoculation wa made 16 days after the beginning of this particular diet. Of 12 animals taken for the experiment, of which 11 were alive at the time of th inoculation, 5 showed tumours ½ cm. in diamete with the exception of one tumour which reache the size of 3 × 1½ cm. In none of these cases wer metastases found.

Experiment IV.—The same experiment wa repeated on a larger scale, controls being use which were fed on polished rice, with a small addition of yeast. For this experiment 15 chicken (Plymouth rocks, as in the previous experiments) age 3 months, were used and were inoculate eight days after the commencement of the particular diet. The result was the following. O 15 chickens fed on polished cooked rice onl inoculated, none developed a tumour. In the cas of addition of yeast, of 13 chickens alive at th time of the inoculation, from the same tumour a the polished rice birds, 8 developed tumours varying in size from 1 cm. to 3 cm. without showin traces of metastases. Experiments on rats inoculated with Jensen's sarcoma showed that a simila diet had identically the same effects as wa observed in fowls inoculated with the Rous sarcom

This whole experiment shows undoubtedly th great influence of vitamine-free and vitamine-containing diet on the growth of Rous's sarcoma.

Experiment V.—The experiments of Murphy an Rous[16] and Murphy[17] have shown that it is possibl to implant Rous's sarcoma into eggs containin chicken embryos and also in the eggs of pigeo and ducks. This shows that either the egg of a species is able to nourish the tumour, or that t embryo has not acquired yet the power of resistan to implanted tumours of foreign species. It wa thought that one-day old pigeons, having perhap a store of embryonic substances, would be susceptible to Rous's sarcoma. Sixteen one-day old pigeon bred in the institute were inoculated with Rous tumour on the second day after their leaving th shell; none, however, have as yet developed a growth. The experiment is being continued.

A SIMPLE AND SUCCESSFUL MEASURE FOR THE PERFORATION OF A GASTRIC OR DUODENAL ULCER.

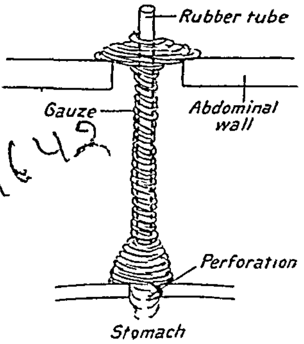
BY EDRED M. CORNER, M.C. CANTAB., F.R.C.S. ENG.,
SURGEON AND LECTURER TO ST. THOMAS'S HOSPITAL AND TO THE CHILDREN'S HOSPITAL, GREAT ORMOND STREET.

ABOUT a year ago, in a paper contributed to the Surgical Section of the Royal Society of Medicine upon the results of operation for the perforation of a gastric or duodenal ulcer and published in THE LANCET,[1] I mentioned a method of dealing with perforation by tamponade. This can be done without any time being spent in attempting to close the perforation by suture. The method is of easy application and can quickly and simply be used by those less experienced in surgery, a very important point nowadays, as so many men practise the art of surgery. Thus it is within easy attainment of the comparatively inexperienced surgeon attached to a minor provincial hospital. Most medical men may be suddenly called upon to operate for the perforation of a gastric ulcer, as, with the cussedness of things in general, the perforations will not occur when a skilled surgeon is about. It is wrong to await the arrival of such a man and so jeopardise the patient's chance of recovery. Last year (1912) a great example of this passed through my hands, an experience which a long journey back to town compelled me to dwell upon, so fixing it in my memory.

One morning I received a warning from Boston in Lincolnshire to hold myself in readiness to depart on a sudden journey there. Later in the day I was asked to come, and arrived in the late afternoon. The patient was a young man, recently married, who had suffered from his "stomach" for some years. About four years ago a gastro-enterostomy had been done by Sir Berkeley Moynihan, of Leeds. This had relieved him for a time. Then came a sudden attack of pain and great collapse. I saw him within 24 hours of the perforation. The abdomen was tightly distended with extravasated gas. There was no liver or any other abdominal dulness. To be short, there was no doubt of the diagnosis. But no operation was allowed by the friends until the surgeon arrived from London. When I arrived the poor man scarcely had any pulse at the wrist. Still, within 24 hours of the perforation so young a man could not be allowed to die without an effort being made to prevent it. So a hurried operation was done whilst the patient was infused with saline. It seems almost needless to add that the patient died after rallying for a time.

After the operation one of the medical men who were so kind as to have assisted me said, "Were not the patient's chances of life lessened by the delay in operation? Would not a less perfect operation which was not delayed be preferable to a more perfect but delayed operation?" Undoubtedly the delay had greatly lessened the patient's chances of recovery. And I must answer the second question by showing that a comparatively simple operation, well within the powers of most to do, is all that is necessary to enable such a patient to live. Also I must thank my professional colleague for his courtesy for referring to my work as a "more perfect but delayed operation." Indeed, I hope to show in this paper that there is no need to use the adjectives "less" and "more" perfect in connexion with an operation for the perforation of a gastric ulcer.

Such an operation must be carried out quickly, and should be shortly described. 1. Open the abdomen below the umbilicus. Examine the appendix and the pelvic viscera. Place a gauze packing in each loin and in the pelvis and leave them there. Free gas may or may not be seen, but odourless greenish-yellow fluid always is. 2. Open the abdomen above the umbilicus—e.g., through the inner part of the right rectus. Find the perforation, mop out any extravasation above and below the liver or round the spleen. Place one end of a gauze "plug" in the perforation to "cork it." Pack a layer or two of gauze plug over the ulcer and wind the rest round a rubber tube which leads out of the wound. (See figure.) 3. Partially close wounds after removing the gauze (draining the pelvis if there is much extravasation).



1642

Diagrammatic representation of the tamponade of a gastric perforation. This method is applicable to any perforation.

In the convalescence do not withhold morphia, but do not use it heedlessly. At first withhold liquids by mouth except water in ounce doses. It will wash the interior of the stomach. A patient on "rectal saline" is in no great want of food by mouth. In 48 hours the drains or "plugs" are removed under an anæsthetic and replaced in part. A gastro-enterostomy is not often needed, and no time is wasted in closing the perforation by suture. So frequently is the tissue round an ulcer too soft to hold stitches that, unless the ulcer can be excised, it is better not to attempt to close the perforation. It is very doubtful how long such stitching lasts, and though apparently secure at the operation it may be loose ten minutes after. Therefore there should always be a drain to the site of the perforation. Indeed, it might be said that the success which has followed the (apparent) suture of a perforation has probably more often been due to the gauze drain than to the suture. So that even better results may be expected when time is no longer wasted in "suturing" the perforation.

In my communication I mentioned that this proceeding had been done many times. Since that date I have done it several times more, proving again its

1649

efficiency. Two instances only will I quote, because they impressed themselves on me by being done in one night and because they bear on the theoretical suggestion that the non-suture of a perforation must lead to the formation of a gastric fistula. This I may say hardly ever occurs, and when it does is only temporary.

One Sunday afternoon I was called to see a lady whose medical adviser, Dr. Ross, had diagnosed the perforation of a gastric ulcer. When I saw her there was nothing except a history of "neuralgic dyspepsia" and tenderness in the epigastric region to suggest that the abdominal calamity originated in the upper abdomen. All the physical signs—distension, rigidity, dulness, immobility, &c.—were in the lower abdomen. On opening the peritoneal cavity nothing of note was found in the lower abdomen. Nothing being found, the upper abdomen was opened, and a perforation found near the lesser curvature on the anterior wall of the stomach. The perforation was large, surrounded by a sodden area of inflamed tissue, and much fluid was issuing from it. The perforation was tamponed in the way described above. Forty-eight hours after the operation the "gastric" gauze was changed, when gas and fluid escaped from the stomach. The issuing fluid smelt like gastric juice, and was more copious when fluid was taken by mouth. It was only mildly septic and interfered little with the healing of the wound. This fistula was present for about ten days, when it healed spontaneously. On my return home, as I opened the front door of my house the telephone rang from Colney Hatch Asylum, where Dr. S. J. Gilfillan told me a nurse was suffering from the perforation of a gastric ulcer. In her case, also, the diagnosis was simple. The operation was also, and was carried out substantially as narrated above. The perforation was much smaller than in the lady just mentioned. Her recovery was very prompt. Her indigestion vanished and her general health has improved very greatly. In neither case was a gastro-enterostomy necessary at the time or has proved to be so later. Indeed, I suspect that in the absence of (narrowing the stomach by) suture, a gastro-enterostomy is less often required than if the perforation is sutured.

These two reported instances are specially selected only because they happened to take place on the same night, and by preventing my getting to bed stamped themselves on my memory as possible examples of results of tamponading the ulcer. Its advantages I will briefly summarise. 1. The operation is simpler for the operator to do. 2. The operation is quicker, particularly in less experienced hands. 3. In consequence of being simpler and quicker, the patient more easily gets over it—that is to say, the mortality is lower. It certainly is so amongst my own figures. 4. A gastro-enterostomy, primary (at the time of the operation for the perforation) or secondary (at a later period), appears to be less frequently required. 5. Complications—e.g., pelvic abscess, subdiaphragmatic abscess, &c.—are in my experience less frequent. Fears of more than a temporary and brief gastric fistula may be dismissed.

If such a summary is in its turn summarised it may be said that such an operation offers the patient more chance of recovery, particularly in the hands of an operator of no great experience. Of course, in the hands of experienced and facile operators the excision of the ulcer, followed by suture of the wound, and perhaps gastro-enterostomy, may be better and result in the recovery of the patient. But for more ordinary patients, surgeons, and circumstances the method of tamponade is better.

Harley-street, W.

NOTE ON THE TREATMENT OF SCIATICA.

BY JOHN J. GRACE, F.R.C.S. ENG.,
CHIEF ASSISTANT, X RAY DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL.

IN view of the great and, I believe, increasing prevalence of sciatica, and the often comparatively poor results obtained from treatment by rest, injections of various kinds, and internal medicine, I think it may be of interest to report the results attained by me during the past year by physical measures—namely, by the use of the 500 candle-power lamp and static electricity. Nine cases have been treated by these methods, eight of which made a complete recovery, but only six of them deserve special mention, as the other three were early acute cases, and the probability is that they would have recovered promptly with rest, drugs, ionisation, or other treatment.

The short history of the six cases is as follows:—

CASE 1.—The patient, aged 53, had lumbago some four weeks previously, but this had got better. He now had cramp in calf and thigh muscles, and severe pain on certain unguarded movements ran down the back of the thigh and was worst at the knee. Knee-jerks present. A patch of anæsthesia, described by him as a "dead patch," on the outer and lower part of the leg, down to the ankle. This patient showed improvement after two or three treatments, but was slow in making a complete recovery. The interesting point was that the "dead patch," which he had had for years, apparently completely recovered.

CASE 2.—The patient, aged 53, who was referred to me for electrical treatment by Dr. T. J. Horder, had had sciatica for two years; had been treated by ionisation, been to the Riviera and Harrogate, &c. Was never very bad, but only exceptionally free from pain for a whole day. He improved very much at first, and then seemed to stick, and just as I was about to despair he recovered completely. This patient was taking medicine as well as having the treatment given by me.

CASE 3.—The patient, aged 64, had sciatica 18 months ago. He went to Vernet-les-Bains and was cured; returned to England and was exposed to cold, with the result that his sciatica returned 13 months ago. The pain was not severe, but always bothered him when he got up in the morning. Slight tenderness over the sciatic nerve between the great trochanter and tuberosity. This patient showed no improvement whatever. His pains became less marked in the region of his sciatic nerve, and increased in the lumbar region and in the anterior part of the thigh. I took a skiagram of the hip-joint, and as there was some evidence of osteo-arthritis in the joint I thought it of little use to continue the treatment. I understand that now, six months later, he still has the pain.

CASE 4.—The patient, aged 57, who was referred to me for electrical treatment by Dr. H. W. McClure, had had sciatica for three months; at first very severe pain night and day; now very severe at times, but not continuous. Always worse at night so that sleep was prevented. There were marked wasting and fibrillary contractions of the muscles of the thigh, less wasting of the calf. Knee-jerks equal. Tender point situated over the sacro-sciatic notch, the internal popliteal, and in the outer side of the calf. Could walk only with the aid of two sticks. After three treatments this patient was having good nights, and after 18 treatments was completely cured.

CASE 5.—The patient, who had had two bad attacks of sciatica lasting for months, came to me complaining of lumbago, but next day said he had cramps in the calves of his legs, and that his previous attack of sciatica had begun in the same way. There was a definite tender point over the left sciatic notch. Treatment was applied here, and also on the right side. After 12 treatments he was able to attend two shoots without apparent damage or relapse.

CASE 6.—The patient, aged 32, three weeks ago with a friend was lifting a heavy weight; the latter let go and the whole weight coming on the patient he strained his back. He had pain in the back for a few days, and this was followed by such severe pain in the sacro-iliac joint that he could not turn in bed, and could get no sleep for five nights. Now he has pain down the outer side of the thigh and calf, and pain in the dorsum of the foot. He could not bend the hip-joint with the knee-joint extended. There was a definite tender point just at the gluteus margin over the sciatic nerve. The patient had a good night after the first treatment, and now after 10 treatments is practically well except for the stiffness.

I should add that all these patients went about their ordinary avocations, as far as they were able to do so, while the treatment was going on. I do not discourage a moderate amount of walking, nor do I object to attention to business. What I do find detrimental to most people is travelling by train or motor car.

The method adopted is as follows. First it is necessary to find the definite tender point or points in the line of the sciatic nerve. These can be found (1) by direction of the patient, (2) by pressure, (3) by the use of the vibrator, and last and best by the use of the static spark; but this latter, if attempted at the first consultation, may unfavourably impress a timid patient.

Having found the tender point, the parts around it are exposed for 20 minutes to the rays of the 500 candle-power light; this is applied as close to the bare skin as the patient can stand the heat, and by turning away the light for a moment, or by passing the hand lightly over the skin a considerable degree of tolerance can be established. The obvious effect is hyperæmia. After 20 minutes' exposure to the light the patient is seated on a chair on the insulated platform. An electrode of some easily moulded metal—I use pewter—is applied over the tender spot, usually about half way between the great trochanter and the tuberosity of the ischium, or over the sacro-sciatic notch. The size of the electrode I generally use is 3½ by 4½ inches, but if the part is very tender a larger electrode will be better borne.

An adequate static machine should be capable of giving a 12-inch spark in all weathers between the terminal balls of the prime conductors when the patient is connected to the machine, and this spark should be capable of regulation down to ½ inch, or less for particularly tender points. With the electrode applied to the patient's skin and connected by a wire to the positive side of the static machine, the negative side being grounded and the spark gap closed, the motor is now started and the spark gap gradually opened, keeping the number of sparks passing at the gap at not more than 300 a minute at the outside, while 200 a minute is even better.

The operator will not have opened the spark gap very far, in all probability, before the patient will complain of pain. When this point is reached the spark gap is closed again until the patient says he feels just a little tenderness, and at this point it is kept for five minutes or so, when the spark gap can again be widened, this time with probably less discomfort to the patient. The treatment by the static wave current is kept up for 20 minutes, or less if the patient shows signs of fatigue. I then go on, if I deem it advisable, to give a few static sparks to the muscles of the buttocks and thigh, to any tender points in the course of the nerve, and to a tender patch probably due to fibrositis, which I often find in the gluteal or lumbar region in these cases.

These sparks are given with the patient standing on the insulated platform, which is connected to the negative side of the machine, the positive side being grounded. A ball electrode held in the hand of the operator and also grounded is approached to within 4 or 5 inches of the spot to which the spark is to be applied. The patient feels a smart blow or cut as with a light whip, and is not apt to appreciate the treatment at first, but after experiencing the relief these sparks bring will often ask to have them repeated and point out the spot where they should be applied.

This ends the treatment, which should be applied daily at first until marked improvement is obtained, when a treatment can be given twice weekly, bi-weekly, and finally stopped. This treatment is equally successful in neuritis of the arm, or in uncomplicated neuritis anywhere when a definite tender point can be found.

As to the rationale of the treatment it is probable that the light causes hyperæmia of tissues deeper than the skin. This hyperæmia followed by the deep massage effect of the static wave current would remove and carry off in the blood current the plastic exudate which is probably thrown out around the nerve in sciatica. The same forces would act in the same way in removing patches of fibrositis.

In addition to this, however, it has been shown that the static wave current increases the hæmoglobin contents of the red corpuscles and increases the elimination of solids in the urine. While I cannot say that I have myself made the necessary observations to confirm these statements, the condition of improved health and vitality in patients who are taking this treatment is so obvious, and so frequently pointed out by them with every evidence of satisfaction, that I cannot feel any doubt but that, in addition to the local effects, general metabolic effects of a beneficial character are taking place in the organism.

" Welbeck street, W.

TWO CASES OF POST-OPERATIVE HEMIPLEGIA.

By A. WEBB JONES, M.D. LOND., F.R.C.S. ENG.,
SURGEON AND GYNÆCOLOGIST, GOVERNMENT HOSPITAL, ALEXANDRIA.

HEMIPLEGIA as a post-operative complication must be so rare that the following two cases which occurred in my practice almost within the same week seem to merit reporting. Both were patients at the Government Hospital, Alexandria.

CASE 1.—The patient was an Egyptian woman, aged 40, suffering from a large fibroid of the uterus. Operation was performed on Sept 15th, 1913, in the raised pelvis position. The tumour involved the supravaginal cervix, which was greatly expanded, and was associated with a tubo-ovarian abscess on the right side. The operation was extremely difficult and lasted almost two hours. A gauze drain was left in for 48 hours. The wound healed without suppuration, but for the first week following operation the temperature was slightly raised, ranging from 37·6° C. (evening) to 37·2° (morning). The operation was done at 9 A.M. At 5 P.M. the patient complained of pain in the right arm and leg, which by the next morning had given place to complete loss of power and sensation. Four days later there was some return of power in the arm, whilst sensation commenced to come back on the twenty-fourth day. Recovery from the paralysis in the arm was good and rapid. Improvement in the lower limb was much slower and less complete, but she left hospital on Oct. 29th walking fairly well with the aid of a stick.

CASE 2.—The patient was an old woman with a large ovarian cyst almost filling the abdomen. The cyst wall had ruptured, setting free a large quantity of colloid material into the general peritoneal cavity. The tumour had evidently undergone malignant changes, and masses like boiled sago had infiltrated the uterus and pouch of Douglas. The cyst was removed on Sept. 22nd, 1913. The operation was simple and lasted less than an hour; there was no shock. The Trendelenburg position was not employed. The operation was performed at 9 A.M. On the following morning she was noticed to have right hemiplegia (including the face) with aphasia. Coma with difficulty in swallowing appeared on the next day, and death took place on the morning of the 26th. On the evening of the 25th the temperature, which had up to that point remained normal, rose to 37·7° C.

Post mortem the entire left cerebral hemisphere showed white softening; there were no signs of hæmorrhage. The aorta above the valve cusps presented slight atheromatous changes. There was no sign of sepsis in the peritoneum.

The occurrence of two such rare accidents so near each other at first suggested there must be some cause common to the conditions under which both operations were done. Beyond the fact, however, that the temperature in the theatre was extremely high and the humidity great, there was no striking peculiarity that I am aware of. Much the same conditions occur every August and September in Alexandria, and besides, on one of the intervening days (Sept. 18th) an ovariotomy for dermoid cyst with twisted pedicle was done by the same *personnel* and followed a normal course.

As regards the cause of the hemiplegia, one naturally first thought of the three common possibilities: hæmorrhage, thrombosis, and embolism. There appears to me to be no special reason why cerebral hæmorrhage should occur *after* operation, although one can imagine that at the time of operation the Trendelenburg position or vomiting might favour such an event. The post-mortem findings, too, in Case 2 put this out of the question. If embolism was responsible one has to imagine that a thrombus displaced from the pelvic veins either traversed the lung capillaries without producing symptoms, or else passed directly to the brain *viâ* a patent foramen ovale or ductus arteriosus. At the necropsy the foramen ovale was not noticed to be patent, but unfortunately the hospital pathologist was not present, and my own attention was not especially directed to that point.

Schenk read a very complete paper on Thrombosis and Embolism following Operation at the American Gynæcological Society in 1913, and the subject was also touched on in the recent discussion on Bland-Sutton's paper on the Visceral Complications in Hysterectomy for Fibroids at the Medical Society of London.[1] One fact appears from the study of these papers, and that is that thrombosis and pulmonary embolism are markedly more common after myoma than after other pelvic operations. Thus, in laparotomies for pelvic conditions of all kinds thrombosis occurs in 2·28 per cent., whereas after myoma operations the percentage rises to 3·7, or even 5 per cent.

With regard to certain theories that have been put forward, it may be mentioned that in both my cases the abdominal wounds were sutured in layers. In the hysterectomy case the retraction of the abdominal walls was vigorous, in the ovariotomy case slight or not at all. It would be out of place to go into the causation of post-operative thrombosis in general, but it appears to me that the anæmic condition of most cases of fibroids may be a predisposing factor, and, furthermore, if slowing of the blood stream be accepted as one of the causes, may not the modern fashion of adopting a semi-recumbent or sitting-up posture increase the tendency in the same direction?

Alexandria.

[1] THE LANCET, Nov. 1st, 1913, pp. 1249, 1256.

SECONDARY HÆMORRHAGE FROM DEEP EPIGASTRIC ARTERY AFTER OPERATIONS FOR APPENDIX ABSCESS.

BY J. O. SKEVINGTON, F.R.C.S. ENG.,
SURGEON TO KING EDWARD VII. HOSPITAL FOR WINDSOR.

I AM not aware that attention has been called to this most serious happening.

On May 15th, 1913, I was called in by Dr. H. E. Giffard, of Egham, to operate on a boy, aged 16, suffering from a large appendix abscess. A secondary operation was required to open a collection of pus per rectum a week later. The boy was making good progress till the evening of the 25th, when I received an urgent message that he was bleeding badly. I found he had lost a large amount of blood, and it was spurting from the lower angle of the abdominal wound. This hæmorrhage was controlled by compression between the finger and thumb till chloroform could be administered. Two deep thread sutures were then passed through the whole thickness of the abdominal wall at the inner edge of the wound, and all hæmorrhage ceased. The boy made a good recovery.

The second case occurred recently and was seen in consultation with Dr. D. H. Anderson and Dr. T. E. Cottu of Maidenhead. The patient, a strong young man, aged 28, had been operated on by Dr. Cottu on Dec. 3rd, 1913, for appendix abscess, the incision being the anterior vertical one through the rectus sheath. He made excellent progress till the afternoon of the 13th, when a large amount of hæmorrhage occurred. Dr. Cottu examined the wound under an anæsthetic, and as the condition of the wound forbade any hope of direct ligature succeeded in arresting the bleeding by plugging. The patient's condition was very serious. When seen the next day in consultation this plugging was removed and there were no signs of hæmorrhage. As the whole area was in a most septic condition, it was judged advisable to keep the patient under close observation and not to disturb the parts further. On the evening of the 16th hæmorrhage again occurred and came from the deep aspect of the abdominal wall at the lower angle of the wound. Ligatures failed to hold, and two large pairs of artery forceps were left on the bleeding spot. This controlled the hæmorrhage, but in spite of transfusion the patient never rallied and died two hours later.

Conclusions.—Both operations were done by the vertical incision through the rectus sheath. In future in all cases in which this incision has to be carried somewhat low down, when the drainage-tube of necessity must lie in close proximity to the deep epigastric vessels, it is my intention to divide these vessels between ligatures when first seen. If immediate suture fails to arrest the bleeding it seems to me the obvious course is to tie the artery through a separate incision. In the first case immediate suture sufficed. In the second case the state of the tissues and the almost moribund condition of the patient forced the expedient of leaving on the bleeding spot a pair of forceps.

Windsor.

RUPTURE OF THE HEART BY EXTERNAL VIOLENCE.

BY ALEX. MILLS KENNEDY, M.D. GLASG.,
ASSISTANT TO THE MUIRHEAD PROFESSOR OF MEDICINE, GLASGOW UNIVERSITY.

CONSIDERING the great frequency of injuries to the thorax, it is remarkable how seldom the heart suffers in consequence. Wounds of the heart muscle may be inflicted by instruments or bullets penetrating the thoracic wall from without, and spontaneous rupture of the heart has been described, usually associated with a pathological condition of the muscle. Injuries to valve segments have resulted in rare cases from blows upon the chest, and Bernstein and Ravenstorf in Germany have both described cases of rupture of the heart by traumatism. Rupture of the heart as the result of external violence to the chest walls is undoubtedly an event of sufficient rarity to warrant its occurrence being recorded.

The patient in the case now reported was brought into hospital in a dying condition, and only survived a few minutes. She was a sparely built, emaciated woman between 60 and 70 years of age; her scalp was almost completely replaced by old cicatricial tissue, which extended down over the forehead and cheeks, and almost wholly replaced the left auricle and closed over the external auditory meatus. No external bruising was present, and the only history obtainable was that of having been knocked down by a cart, one shaft of which had probably struck her in the right mammary region. Possibly an hour had elapsed from the time of the accident till her death in the reception room of the hospital.

A necropsy was made 48 hours later, and the following report summarises the conditions found.

Thorax.—The second, third, fourth, fifth, and sixth ribs of the right side were fractured, each about ½–¾ inch from the costo-chondral junctions. The anterior fragments of the third and fourth right ribs were driven inwards into the thoracic cavity for a distance of about ½ inch, but the costal pleura over their ends was not ruptured. There was some hæmorrhage into the subpleural tissues over the sites of these fractures. The fourth right costal cartilage was fractured through its junction with the sternum. From the lower border of this latter fracture another fracture arose which passed across the sternum to terminate at the upper edge of the fourth left costal cartilage. There was no tearing of the tissues in the immediate neighbourhood of this sternal fracture. The sixth left rib was fractured at a point 1½ inches from its costo-chondral junction; the costal pleura was thereby torn, and there was a little hæmorrhage into the subpleural tissues in the immediate neighbourhood.

Pericardium.—About 10 ounces of fluid blood were present in the pericardial sac, but the pericardium was otherwise healthy.

Heart.—There was slight general dilatation of the heart, and the cardiac muscle was pale and soft. A microscopical examination of the cardiac muscle revealed some brown atrophy of the muscle fibres, but this could not be considered more excessive than one would expect in an individual of this age. No valvular lesions were present, and the coronary arteries were healthy. Patches of atheroma were present throughout the aorta. In the anterior wall of the left ventricle there were two ruptures, half an inch apart, extending across the wall parallel to one another in a horizontal and downward direction from the middle line outwards. The edges of these wounds were somewhat irregular and ragged.

The *upper wound* measured 1½ inches long on its epicardial surface, and extended right through the wall of the left ventricle and caused some tearing of two branches of the anterior papillary muscle. Its endocardial orifice measured only about ¾ inch. The inner end of this wound was situated ½ inch to the left of the interventricular groove and 1 inch below the auriculo-ventricular groove; its outer (or left) end was 1¼ inches below the auriculo-ventricular groove and reached to within ¼ inch of the left border of the heart. The *lower wound*, lying ½ inch below the upper, was ½ inch long and extended to a depth of only ⅛ inch. Its inner end was about the same distance from the interventricular groove as that of the upper wound. Above the upper wound, extending up to the auriculo-ventricular groove, there were some patches of hæmorrhage under the epicardium, and there was also hæmorrhage into the tissues of the superior mediastinum around the origins of the great vessels from the aorta. There were no other injuries present anywhere.

The *lungs* showed emphysema and some old cicatrisation at both apices with a few adhesions. The *spleen* was slightly enlarged and soft, and the *kidneys* granular, but none of the other organs showed anything of note.

The case presents several features worthy of remark. There can be little doubt that the blow on the chest was delivered with considerable violence, yet there was no bruising visible externally. The chest wall was freely mobile and the transverse fracture of the sternum corresponded in level more or less closely with the rupture of the wall of the left ventricle, yet the parietal pericardium was intact, and there was no tearing of the tissues in the immediate neighbourhood of this fracture. There was no gross disease of the coronary arteries or of the cardiac muscle, and the brown atrophy made out microscopically in the fibres of the latter was probably normal for a person of such years. Considering these facts along with the characters of the wound—the irregular and ragged edges—and the tearing of two branches of the anterior papillary muscle, it seems reasonable to assume that the mechanism of the lesion was rupture by bursting.

Glasgow.

CENTENARIANS.—There are at least four centenarians living in Surrey, according to the *Surrey Advertiser*—Mrs. Stovold, of Elstead, and Mrs. Ann Peters, of Great Bookham, who have just celebrated their hundredth Christmas; Mr. John Durant, of Weybridge, who attains his 104th birthday on Feb. 2nd; and Mr. John Whitehead, of Wimbledon, who is 100 years of age. Mrs. Rose Wood, of Chertsey, died on Dec. 31st last. She would have completed her 103rd year had she lived till March next. Miss Emma Elkins, who in July last entered upon her 101st year, died recently at Prestbury, Gloucestershire.

Medical Societies.

LIVERPOOL MEDICAL INSTITUTION.

Hypermetropic Astigmatism.—Sclero-corneal Trephining for Glaucoma.—New Operation for Treatment of Salpingitis.—Some Factors in the Spread of Typhoid Fever.

A MEETING of this society was held on Dec. 18th, 1913, Mr. **ROBERT JONES**, the President, being in the chair.

Dr. **R. E. HARCOURT** related the case of a youth, aged 19, in whom Hypermetropic Astigmatism was present, with hystero-epileptic fits and headaches over a period of six weeks. Rest in bed caused the fits almost to cease, and correction of the refractive error resulted in complete cessation of fits and headaches.—Dr. **H. ARMSTRONG** mentioned the case of a child, aged 4, in whom homicidal mania was present along with hypermetropia and squint. In this case correction of vision had also resulted in complete disappearance of all mental symptoms.

Dr. **A. NIMMO WALKER** read a note on Further Experiences of Sclero-corneal Trephining for Glaucoma. He described three important modifications of the operation originally performed by Lieutenant-Colonel R. H. Elliot; the flap was altered in shape, being made a small segment of a large circle parallel to the limbus; the trephine hole was made further forward, and the iris was allowed to prolapse into the trephine hole, a small portion being snipped out with scissors and the prolapsed portion allowed to fall back into its place. Dr. Walker was of opinion that this operation was by far the best treatment yet discovered for glaucoma. He did not claim that it was an infallible cure for all cases, but it enabled the surgeon to advise an operation which had a good chance of arresting the disease without causing mutilation of the eye or damage to the sight. A patient was shown on both of whose eyes the trephining had been performed.—Mr. **R. J. HAMILTON** had seen two cases where the drainage had not continued after the trephining and iridectomy had then been done. He had had good results in other cases.—Mr. **HUGH E. JONES** had found iridectomy satisfactory, but considered that in some cases tension was kept down better by trephining.—Dr. **EDGAR STEVENSON** considered that the introduction of the trephining operation was the most important step forward in ophthalmology since von Graefe introduced iridectomy. The operation was all British.

Dr. **W. BLAIR BELL** described a New Operation for the Treatment of Severe Salpingitis in Young Women. As the internal secretions of the ovary and the menstrual function were important in the general condition of young subjects he did not in them approve of complete removal of the tubes, ovaries, and uterus. By taking a wedge-shaped portion of the fundus along with one ovary and both tubes he removed the diseased structures, and left enough to be of use to the patients.

Dr. **C. O. STALLYBRASS** read a paper on Some Factors in the Spread of Typhoid Fever. He showed by large charts that the great fall from 1300 cases in 1895 to 124 in 1912 was coincident with the fall in the number of courts and alleys in the city. The greater facilities for the isolation of the sick, the supervision of the milk-supply and that of other foodstuffs, and the removal of fly-breeding refuse had also contributed. Many cases were imported, mainly sea-borne, and these might be the source of small local outbreaks, especially where one of the patients was a chronic carrier. Dr. Stallybrass had found shell-fish cases to be due mostly to mussels from Ireland. Oysters had not for some time given rise to typhoid fever so far as was known. In his opinion typhoid fever was chiefly spread by direct contact, fingers of a patient or his attendants being soiled by excreta, and in many cases food prepared by the soiled hands led to spread of the disease. He thought it possible that flies might carry germs to food and so cause infection. It might yet be proved that biting insects also spread the disease.—Dr. **E. W. HOPE** said that Dr. Stallybrass's careful work proved and confirmed the views of the causation of typhoid fever. It had been suggested that the disease was decreasing because the population was acquiring immunity, but the facts presented proved this was not the case; 65 per cent. of notified cases had had their origin determined accurately.

DEVON AND EXETER MEDICO-CHIRURGICA SOCIETY.—A meeting of this society was held at the Roya Devon and Exeter Hospital on Dec. 12th, 1913, Mr. Russel Coombe, in the absence of the President, being in the chai —Dr. Ransom Pickard and Mr. G. L. Thornton showed case of Third Cranial Nerve Paralysis with some unusua points of interest. The patient, a married woman aged 46 was suddenly seized with severe pain in the head and back o the evening of Dec. 19th, 1912. Mr. Thornton was called i shortly after the onset. The patient had vomited and ha felt as if her whole body was in a vice, but the pain wa now most severe at the vertex. She had taken a dose o castor oil which might possibly have accounted for th vomiting. The temperature and pulse were within norma limits, and a routine examination failed to reveal an definite cause for the pain. A freely movable right kidne was noted and a Dietl's crisis was queried. The family an personal histories were unimportant, the only point to not being a chronic nasal catarrh of the left nostril and deflected septum to that side, for which she had bee treated. On the following day the headache was relieved although it had not entirely disappeared, but the pain no was chiefly referred to the lower sacral region, and sh could not sit long in one position. This pain became aggra vated on Christmas Eve, and when playing cards she notice for the first time that the figures ran together and she also sa double. By 10 P.M. the left eyelid had completely droppe When called to see her on Dec. 26th there was found to b complete paralysis of the left third nerve. The temperatur and pulse were normal. There was no reflex alteration c abnormality other than that related directly to the affecte nerve. The patient's subjective symptoms were pain in th back, of lumbago nature, and some stiffness. The case wa watched carefully for some days, the patient being kept i bed. No rise of temperature was noted, and the pain in th back gradually abated, and but for the eye symptoms th patient was in her usual good health in three weeks fro the onset of the illness. Total paralysis of the ner persisted until May, when slight raising of the l was first noticed, and from this time onwards gradu progress was made as regards the movements of the muscl involved. Improvement during the last three months ha been almost at a standstill. The fundi oculi had been foun normal throughout. The points of interest were chiefl centred in the diagnosis. The onset suggested an acut infection, but the absence of pyrexia was certainly unusual. Polypi in addition to the nasal discharge had been noted in the left nostril and the possibility of nasal infection could not be ignored, although it was difficult to understand how the accompanying nerves should have escaped when considering a sphenoidal sinus infection. In the same way hæmorrhage was unlikely. Other suggestions had included a rheumatic origin comparable with that in Bell's palsy. The pain in the back could not be ignored, although the symptoms present were not sufficient to warrant a diagnosis of meningitis. Specific disease could be disposed of entirely, as apart from the extreme improbability the Wassermann test had been found negative by a competent authority. The treatment adopted had been salicylate with hydrargyri perchloridum and iodide, and later strychnine. Locally galvanism had been applied to the lid and directly to the eyeball, as suggested by Dr. Risien Russell.—In the discussion which followed Dr. W. Gordon pointed out the necessity for a guarded opinion when these cases were seen at an early stage. The possibility of disseminated sclerosis should be borne in mind. As regards the case in question, a rheumatic origin appeared to be the most likely diagnosis.—Mr. R. A Worthington asked if the nasal discharge had been purulent in character and whether investigations had been made with regard to the condition of the sphenoidal sinus.—Dr. Gordon read a paper on the Value of the Cardiac Sign in Cancer—50 consecutive cases with 8 per cent. of error.—Dr. R. V. Solly, in discussing the paper, pointed out the unreliability of the presence of Foule's cells in the peritoneal exudate.—Mr. Worthington said there were three points of view in considering changes in cardiac dulness—(1) heart's diminished size; (2) emphysema; and (3) dislocation of the heart. The pericardium may become laxer under certain conditions, and the attachments of the heart in like case loosened. It was possible to his mind that the sign was due to slackening of the pericardium and to some extent relative to advancing age—

a component factor in loosening of ligaments and in the incidence of cancer.—Dr. F. A Roper thought that more thorough investigations should be made of gastric contents in suspected cases of cancer. He also alluded to the alkalinity of the blood test and to Salmon's test for total free nitrogen in the stomach contents —Dr Gordon replied —Mr O E W Bell showed a Pregnant Uterus which he had removed owing to complications related to the presence of a large fibro myoma —Dr. J. D Harris exhibited X Ray Negatives as viewed with the radioscope.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY —A meeting of this society was held in Manchester on Dec 19th, 1913, Dr W E Fothergill, the President, being in the chair.—Dr A Donald (Manchester) showed a specimen of Endothelioma of the Cervix occurring in a woman aged 25, removed by abdominal panhysterectomy —Dr W Blair Bell (Liverpool) showed a specimen of an Unusual Malformation of the Uterus This uterus was apparently normal except for a small left horn to which were attached the round and ovarian ligaments Dr. Bell also showed a specimen of an Ampullary Pregnancy on the point of rupture —Dr H Clifford (Manchester) reported a case of Concealed Accidental Hæmorrhage accompanied by hæmorrhage into the peritoneal cavity apparently due to rupture of vessels in the right broad ligament following the great and acute distension of the uterus The patient was admitted to hospital in a very serious condition, and after a short rest it was decided to open the abdomen and remove the uterus This was rapidly done and for a short time the patient rallied, but eventually died six hours after the operation The urine was loaded with albumin —Dr H Leith Murray (Liverpool) and Mr R. M Littler (Southport) recorded a case of Adeno chondrosarcoma of the Endometrium occurring in an unmarried woman aged 46 Microscopical examination of a polypus suddenly extruded from the cervix rendered the diagnosis easy and a wide hysterectomy was done Regular glands, sarcoma spindles, islands of hyaline cartilage, and possibly fat cells were present There was no invasion of the cervix, the muscularis of the body, or the appendages

BRISTOL MEDICO-CHIRURGICAL SOCIETY —A meeting of this society was held on Dec 10th, 1913, Dr. P Watson-Williams being in the chair —Mr H Elwin Harris showed a child with Chronic Tertiary Ulceration of the Scalp —Dr J O Symes showed a patient with Multiple Swellings in and on the Tibia and other Bones, with a proteid body in the urine The patient was improving with antispecific treatment, and the Wassermann reaction was positive —Dr E C Williams stated that an infant, aged 5 months, with a Gumma of the Femur, which he was to have shown, had died 41 days after an injection (intramuscular) of 0 05 gm of neosalvarsan —Dr Carey F Coombs, in showing a case of Associated Tabes Dorsalis and Aortic Regurgitation, remarked that this was the not uncommon "Babinski" syndrome, and that syphilis was probably the cause of aortic disease in 75 per cent of cases —Dr. Bertram M H. Rogers showed an infant, 2½ months old, in whom all symptoms had cleared up and the child put on weight after an intramuscular injection of 0 05 gm of neosalvarsan —Dr Watson Williams showed patients illustrating typical tertiary syphilitic lesions of the nose, pharynx, and larynx —Professor J Michell Clarke showed a case of Associated Congenital Syphilis and Graves's Disease, and said that he regarded the simultaneous occurrence as accidental —Dr J R Charles showed a case in which there were symptoms of tabes in association with plumbism and a positive reaction might possibly be due to the lead —Dr J R Kay-Mouat among other specimens showed one of the site of injection of salvarsan 19 days after injection The tissues showed the presence of arsenic in the centre with a surrounding area of hyperæmia and leucocytic infiltration

THE ASSOCIATION OF ASSISTANT MEDICAL OFFICERS OF ASYLUMS IN ENGLAND AND WALES —The following office-bearers in this newly formed association have been elected.—Chairman. E L Dunn, Berkshire Asylum, Wallingford Honorary treasurer W Maule Smith, 2, Victoria-road, Bromsgrove Honorary secretary: F. J Stuart, Berry Wood, Northampton.

Reviews and Notices of Books.

Researches on Rheumatism.

By F J POYNTON, M D Lond, F R C P Lond, Senior Physician to Out patients at University College Hospital, London, and at the Hospital for Sick Children, Great Ormond street, Physician in Charge of the Children's Ward, University College Hospital; and ALEXANDER PAINE, M D Lond, D P H, Director of the Cancer Hospital Research Institute, London London J. and A. Churchill 1913 Pp 461 Price 15*s.*

IN this volume Dr. F. J Poynton and Dr. Alexander Paine have collected together the chief papers bearing upon a research on the subject of rheumatism with which they have been occupied for a period of 15 years The results obtained by these two observers are well known, and as their published writings are scattered through the medical press for many years, the authors have performed good service in bringing them into one volume.

The greater part of the book is concerned with the details of the acute rheumatism of childhood, this condition being chosen because it is frequent in its occurrence and also not uncommonly fatal, and thus clinical, pathological, and histological facts can be obtained As is well known, Dr. Poynton and Dr Paine maintain that acute rheumatism is a specific disease caused by a definite micro organism. Their views have met with a considerable amount of criticism owing to the negative results that have been obtained by some bacteriologists, but, on the other hand, they have been corroborated by others. One great difficulty has been to define the condition acute rheumatism, for unfortunately numerous disorders are covered by the all embracing term "rheumatism" The authors, however, save themselves from falling into the trap of believing that everything met with showing the least resemblance to acute rheumatism is in reality of that nature

The work is divided into three parts Part I contains papers published between 1898 and 1900, previous to the demonstration of the diplococcus, which Dr. Poynton and Dr Paine now look upon as the causal organism of acute rheumatism. In Part II. the papers deal with the demonstration of the bacterial cause of acute rheumatism, the nature of the rheumatic processes in man and animals, the bearing of the results obtained upon conditions allied to the rheumatic, together with some investigations into such conditions This group is subdivided into a group dealing with the cardinal steps in the demonstration of the etiology and into others dealing with arthritis, chorea and other nervous manifestations, and with heart disease. The last of these groups contains the practical applications of the investigation to clinical medicine and public health. Part III consists of a study of acute rheumatism based upon the results of the previous researches, and has not been published before It forms a valuable summary of the present knowledge on acute rheumatism, with a brief review of the investigations which led up to the same

In discussing the etiology the theory of infection is naturally considered, and whilst upholding the view that the disease may be looked upon as the result of infection by a diplococcus belonging to the streptococcal group, Dr. Poynton and Dr. Paine do not maintain that the causation of acute rheumatism is due entirely to the invasion of this organism. Its presence in the tissues is, they think, essential, but there are important predisposing factors of much practical interest, amongst which may be mentioned heredity and age incidence. Further, they say that in general those surroundings which are associated with poverty and neglect are responsible for much of the acute rheumatism so rife in this country.

A brief account is given of the chief characteristics of the diplococcus rheumaticus. The morbid anatomy is then considered, including not only the changes in the joints and connective tissues, but also the subcutaneous nodules and the state of the respiratory system, especially the tonsils, and the opinion is expressed that unhealthy conditions of the tonsils and nasopharynx are, especially in childhood, closely associated with acute rheumatism.

In the section dealing with symptomatology two general statements are made—the first, that in the future all descriptions of acute rheumatism will be probably based upon a survey of the disease in the young, and such peculiarities as occur in adult life will be looked upon as departures from the classical disease which is seen in its truest characters in childhood; the second, that the symptoms do not always combine to produce an acute disease running a definite course. On the contrary, not only may the symptoms be at first indeterminate, but they may even occur as isolated events pointing to the implication of one important organ only. Indeed, the authors suggest, with some reason, that any description of the symptoms of acute rheumatism must be almost as formidable an undertaking as a description of tuberculosis.

The last point dwelt upon is the influence of these researches upon the all-important problem of the treatment of the disease. Amongst drugs the administration of the salicylates naturally receives most attention, and whilst admitting that these remedies relieve pain and lower temperature, the authors fail to find any proof that they have a specific action; therefore, although advocating their use for the polyarthritis, muscular pains, or headache, they do not advise pressing them for their specific action in heart disease or chorea. Stress is laid on the importance of adopting all possible measures for the prevention of the disease, such as proper clothing and care of sore throats. In conclusion, Dr. Poynton and Dr. Paine express their conviction that the general subject of "rheumatism" has reached only the threshold of inquiry, and that in every direction new fields for research and inquiry are open.

This volume will be found of unusual interest, containing as it does a large amount of instructive information, and throwing out many suggestions for future investigation. The authors may be congratulated on their patient and thorough research.

Epidemic Cerebro-spinal Meningitis.

By ABRAHAM SOPHIAN, M.D., formerly of the New York Research Laboratory. With 23 illustrations. London: Henry Kimpton. Glasgow: Alexander Stenhouse. 1913. Pp. 272. Price 12*s.* 6*d.* net.

THIS monograph is the outcome of the exceptional facilities enjoyed by the author of studying epidemic cerebro-spinal meningitis clinically during the Texas epidemic of 1912 and pathologically and experimentally in the New York Research Laboratory under the ægis of Dr. Simon Flexner. His purpose is to convey a thorough yet simple description of the clinical and laboratory findings, and to familiarise the reader with the application of laboratory methods to the treatment of the disease. In this purpose he has amply succeeded.

The etiology, symptomatology, and laboratory diagnosis of the affection are entered into at considerable length, and there are important chapters on the complications of the malady and on its treatment. The last of these occupies no fewer than 98 pages, and constitutes one of the best and most comprehensive discussions of therapeutic and prophylactic measures in the disease under consideration in the whole literature. There is a detailed description of the author's new method of administering anti-meningitis serum subdurally. The complications met with in cases of "dry canal" and where the intrameningeal exudate is very thick and plastic are dealt with, as well as the hydrocephalus that occurs in the acute stage. The whole chapter is replete with practical suggestions, and demonstrates afresh the value of scientific research in the furtherance of clinical medicine.

The monograph contains an excellent account of the present state of our knowledge of epidemic cerebro-spinal meningitis; both clinical and pathological illustrations are well reproduced, and the index is good. The author's acquaintance with the literature is wide, but while the work of many previous investigators is constantly referred to, there is a regrettable absence of information as to where their papers are to be found. There are some minor blemishes—misprints and inaccurate grammatical constructions, and several French and German words are incorrectly rendered.

Psychology Applied to Legal Evidence and Other Constructions of Law.

By G. F. ARNOLD, I.C.S., C.I.E., late Member of the Burma Legislative Council. Second edition, revised and re-written in parts. Calcutta: Thacker, Spink, and Co. 1913. Pp. 607. Price 12 rupees.

THE fact that this work has reached a second edition—it was first published in 1906—is a proof that the author's uncompromising attack on the legal system under which he has worked has excited the interest, even if it has not won the approval, of a sufficient circle of readers. To many, however, it is possible that the severity of Mr. Arnold's criticism may appear somewhat excessive, for, though it is common enough to hear grumbles at the delays and eccentricities of the law, there is little evidence of any very intense and widespread dissatisfaction with the administration of justice in this country. It may be, of course, that Mr. Arnold's official career in the public service of India has made him more keenly aware of the imperfections of the English legal system than he would have been had he seen it in operation only in the country of its origin. Founded as that system is on the exaggerated intellectualism of Western civilisation, its application to Oriental races of totally different psychological type can hardly be expected to produce invariably good results; and an observer who failed to bear that qualifying consideration in mind might be easily led to attribute to the faultiness of our jurisprudence what ought more justly to be ascribed to its unsuitability to the Asiatic temperament. Some such explanation seems the most obvious way of accounting for the vigour, not to say violence, of Mr. Arnold's sweeping condemnation of English law and English lawyers; and this view will appear the more probable from the fact that most of the concrete instances of legal ineptitude which he cites are drawn from the records of Indian courts. The author, however, does not himself suggest any such limitation of his criticism, which is of a more general character and is concerned with the fundamental principles of the legal system. It is under this wider aspect, therefore, that we have to examine his arguments.

The main count in Mr. Arnold's indictment is that the law *fails to* make use of the conclusions and methods of other sciences, and more particularly of the conclusions and methods of psychology, which, as being the science that deals with mental qualities, human motives and conduct, should be in a special manner the guiding influence in legal theory and practice. It is Mr. Arnold's contention that, so far from admitting and acting upon this self-evident principle, lawyers as a class have constantly displayed a bigoted prejudice against all branches of philosophy, with the result that, when legal methods are examined from the standpoint of modern psychology, they are found to be hopelessly antiquated and faulty, out of harmony, not merely with the more recent conceptions of science, but even with such general knowledge of the mechanism of thought and action as the average citizen uses in his ordinary dealings with his fellows. Developing this idea, the author attacks the legal system for its artificiality of language, its insistence on forms and precedents, its rigid rules of evidence, its principles of interpretation and procedure—in short, for all the characteristic features which lawyers are wont to insist upon as constituting its special strength. That there is a large element of truth in this criticism is indisputable. It is clearly impossible, for instance, to defend that obstinate adherence to the tenets of an extinct psychology which insists on retaining as the criterion of criminal responsibility the absurd rules laid down in the Macnaghten case; and it matters little that in this question legal practice is usually better than legal theory; indeed, the fact rather supports Mr. Arnold's thesis, as proving the strength of that exaggerated conservatism which he imputes as a special vice in the law. And, as the author very acutely shows, the same intellectualist fallacies which have determined the legal attitude with regard to insanity have inspired many other legal views; they are implicit, for instance, in the authoritative doctrines with regard to intention.

It may be freely admitted, therefore, that Mr. Arnold, in this application of psychology to the criticism of law, has on many points made out a good case for his iconoclastic views. And yet his work leaves on the whole an unsatisfactory impression, and just for the reason that it is purely iconoclastic. In his preface Mr. Arnold has anticipated this objection, but he has not answered it, and, indeed, it hardly admits of a convincing answer. In a purely theoretical question an exclusively destructive attitude may, no doubt, be perfectly legitimate; but the law is not a branch of abstract knowledge; it is a practical system evolved by society to serve its self-protective purposes, and it has of necessity the imperfections that belong to its mode of origin. The critic who points out these imperfections, but fails to suggest how they are to be made good, is at once open to the rejoinder that the evils which he deplores may be inevitable in so purely empirical a creation as every legal code must necessarily be. At all events, the existence of such evils can hardly be, as Mr. Arnold sometimes seems to suggest, a sufficient reason for doing away with the legal system, root and branch. When due allowance has been made for the tendency which he occasionally shows to press his criticisms to rather extreme lengths, Mr. Arnold may be congratulated on having produced a valuable and stimulating study of this subject.

Embolism and Thrombosis of the Mesenteric Vessels.

By LESLIE B. C. TROTTER, M.A., B.C. Cantab. Cambridge: The University Press. 1913. Pp. 143. Price 8*s.* net.

THIS book forms an exhaustive study of mesenteric vascular occlusion, presented as a thesis for the doctorate. The author was stimulated to the research by having under his care two cases, but later he increased the number of his original cases to seven, and amended these by collecting and critically analysing in all 360 cases from various sources. The original cases are described in detail and illustrated, and then the whole subject is treated of under the heading of morbid anatomy, which forms the basis of classification, experiments, descriptive anatomy, symptomatology, diagnosis, and treatment.

The author found the most common cause of arterial occlusion to be embolism following lesions of the heart and arteries, whilst venous thrombosis was most commonly found spreading from thrombosis of the portal vein, though in some cases it arose primarily as a result of an infective process in the intestinal tract or in the pelvic organs of the female. The duration of the condition was from two days to a fortnight, whereas the symptoms appeared to be those of acute abdominal mischief. The treatment adopted was that of immediate laparotomy, but it was found that 36·2 per cent. of recoveries resulted from all cases of operation. There are an extensive bibliography and a list of 366 cases.

The compilation added to the careful account of the author's own cases has considerable value. Indeed, if such clinical (using the word in its widest sense) investigations more frequently formed the subjects of theses, much good would accrue to practical medicine.

Handbuch der Frauenkrankheiten.

Von M. HOFMEIER, Professor der Geburtshilfe und Gynäkologie in Wurzburg. With 290 illustrations and 10 plates. Leipzig: F. C W. Vogel. 1913. Pp. 628. Price 14 marks, or bound 16 marks.

BUT little need be said of so well-known a German text-book as this of Professor Hofmeier, more especially as this edition corresponds to the fifteenth edition of Karl Schroeder's book on diseases of women, upon which it was originally based and which it now represents.

The whole work has been well and carefully revised, a great deal of new matter has been incorporated, and a quantity of old eliminated. The number of illustrations has been increased by 22, and many of the old ones have been redrawn. A new chapter has been added on the treatment of gynæcological cases by X rays. As the author rightly remarks, sufficient time has not yet elapsed to allow us to determine with certainty the place which this therapeutic agent will ultimately take, but the results so far obtained by its use are very encouraging. The main indications recognised are hæmorrhage at the menopause and that due to fibromyomata of the uterus. A less definite indication is afforded by cases in which artificial sterility is desired such as tuberculosis, and cases of disease of the external genitalia. It is also suggested that good results will attend its use in cases of peritoneal tuberculosis and as an adjunct to the use of radium or mesothorium in cases of carcinoma of the uterus. A number of interesting and encouraging statistics are quoted from the various German cliniques in which this mode of treatment is being carried out. Attention is called to the dangers of burning of the skin and of setting up excessive hæmorrhage as the first result of the use of the rays, but nothing is said of the risks of setting up inflammatory changes in the peritoneal cavity and the possible production of changes in the intestinal mucosa and the formation of adhesions. The author lays stress upon the necessity for large doses of hard rays, and points out that small doses of soft rays produce imperfect and disappointing results.

The whole book is a good example of the best type of German text-book.

Normal Histology. With Special Reference to the Structure of the Human Body.

By GEORGE A. PIERSOL, M.D., Sc.D., Professor of Anatomy in the University of Pennsylvania. Tenth edition. With 438 illustrations, 88 of which are in colour. London and Philadelphia: J. B. Lippincott Company. Pp. 418. Price 15s. net.

THE eighth edition of this work was reviewed in THE LANCET of Feb. 11th, 1911. The number of pages in the present edition is exactly the same as in the eighth, and the preface bears date, August, 1910. What we said of the usefulness of the work in 1911 remains equally true of the new edition, but some of the coloured illustrations in this new edition do not seem to us to be quite so effective—e.g., the chromatic figures in dividing cells of the epidermis, where one colour is used with a deepening of the same colour for the chromosomes; and the same is true of a section of young periosteum and the adjacent bone. The other two-coloured illustrations of bone are distinctly more effective. The complex maze of cells and colloid of the pituitary body would stand out much better if the figure had been printed in colours. Others in monotone, such as red, might almost as well have been given without colour.

Dynamische Biochemie, Chemie der Lebensvorgänge.

Von Dr. SIGMUND FRANKEL, A.O. Professor für Medizinische Chemie an der Wiener Universität. Wiesbaden: J. F. Bergmann. Pp. 600. Price M 18.60.

THIS volume proves the rapid developments which have taken place as the result of the conjoint studies of the physiologist and chemist in regard to the great vital processes. The author is recognised as one of the pioneers in bio-chemical research, and it is evident from the pages in this volume that his own original contributions have filled important places in the story so far as it has advanced. Dr. Fränkel has conducted inquiries of a practical nature on such subjects of importance as adrenalin, cholin, the lipoids, phosphatides, amino-acids, and the reducing and oxidising processes in the tissues which are concerned in metabolism. He shows, as might have been expected, a wide-ranging familiarity with the many subjects embraced in the title of this volume.

The book contains 13 chapters. The first is devoted to the physical and chemical processes involved in the tissues. This is followed by a consideration of the special chemical changes in the organism (oxidation, synthesis, and reduction). Then succeeds a chapter on the ferments, and afterwards sections on digestion, resorption, assimilation, metabolism, the classification of food substances, the chemical functions of the individual organs, the secretions, physiology of the sexual organs, muscle, nerve, skin, kidney, and the blood. The whole concludes with a comprehensive chapter on immune chemistry. There are busy workers in the field of bio-chemistry in all countries having any pretension to occupying a place in the world's science, and therefore no collection of materials can be complete without a copious reference to these international endeavours. Dr. Fränkel recognises the importance of such references or he would not have included, with the pains he has done, what amounts to a guide to the universal literature on the subject in the numerous footnotes given. The work is authoritative and the various presentations of the subject are adroit as well as learned.

LIBRARY TABLE.

Mendelism and the Problem of Mental Defect. I. A Criticism of Recent American Work. Department of Applied Statistics, University College. "Questions of the Day and of the Fray," No. VII. By DAVID HERON, D.Sc. London: Dulau and Co. 1913. Pp. 62. Price 2s. net.—The American papers dealing with the inheritance of mental defect which come in for the bulk of the criticism contained in Dr. Heron's pamphlet are three in number—(1) A First Study of the Inheritance of Epilepsy, by Dr. C. B. Davenport and Dr. D. F. Weeks (Eugenics Record Office, Bulletin No. 4); (2) The Inheritance of Epilepsy, by Dr. Weeks (Problems in Eugenics, p. 62); and (3) Chapter IV. of "The Hill Folk," by Miss F. H. Danielson and Dr. C. B. Davenport (Eugenics Record Office, Memoir No. 1). His reasons for devoting so much space and time to their criticism are that "they have been welcomed in this country as of first-class importance," and that their teaching is fallacious. In the first paper the theory was stated rather dogmatically that feeble-mindedness and epilepsy considered together as one character behaved in inheritance as a simple Mendelian recessive. That this work had previously been received without criticism in this country is not in point of fact the case, as Dr. Heron will discover if he refers, for example, to the *Eugenics Review* for July, 1912. In the second paper the conclusions are much more modestly stated, and in the third the theory is abandoned altogether and another more complex hypothesis substituted with the warning that, "in view of the difficulties in analysing individuals [presumably the members of the 'Hill Folk' are here referred to] accurately the study of the inheritance of their traits can only be suggestive." It is impossible to give briefly any account of Dr. Heron's criticism. Much of it appears as regards its substance perfectly justified. Some of it, on the other hand, is hardly fair—as, for example, when he finds fault with Dr. Davenport for inconsistency because he has changed his mind. The whole of it would have been more effective if it had been expressed with less rancour and less rhetoric.

A Companion to Manuals of Practical Anatomy. By E. B. JAMIESON, M.D. Edin., Senior Demonstrator and Lecturer on Anatomy, University of Edinburgh. London: Henry Frowde and Hodder and Stoughton. 1913. Pp. 543. Price 6s. net.—Dr. Jamieson has added another pocket anatomy to the student's outfit. This volume, like all of its class, is intended to assist the student in revising work already done properly both in the dissecting room and with the larger text-books. It shares the danger common to all these little books—that it may degenerate into a mere cram-book for the student who has not so done his work. Indeed, the transition is a perilously easy one. We trust that the student into whose hands this volume falls will respect the author's aims, and use it only after his foundation work has been properly and truly laid.

Text-book of Anatomy and Physiology for Nurses. By AMY E. POPE, Instructor in the School of Nursing of the Presbyterian Hospital in the City of New York. With 135 illustrations, many in colours. New York: G. P. Putnam's Sons. 1913. Pp. 554. Price 6s. net.—Anatomy and physiology are subjects of which the nurse should rightly have some fundamental knowledge, but the proper setting of these subjects for the use of nurses seems to be a particularly difficult problem. In the present instance we note with disfavour the condensing of highly important knowledge into "tips" (or, as the author puts it, "doggerel") not worthy of print, and degrading to memory. We also note that the illustrations are derived from Testut's great work, but that those that are acknowledged are ascribed to Professor F. H. Gerrish, who familiarised them to American readers.

Über den Hospitalismus der Säuglinge. Von D. LUDWIG F. MEYER, Privat-dozenten an der Universität, Berlin. With 31 figures in the text. Berlin: S. Karger. 1913. Pp. 78. Price 4 marks.—The author regards the so-called hospitalism of nurslings as due mainly to three different factors—intestinal infection, improper feeding, and insufficient care. After considering these three factors in detail he illustrates the pernicious influence of the hospital upon such children by observations carried out in the orphan asylums in Berlin. Great stress is laid upon the frequency of diseases of the air passages in nurslings and the disastrous effects of errors in feeding. In conclusion, the author points out that a lowered mortality rate is only to be obtained by the prevention of affections of the air passages and improvements in the methods and technique of artificial feeding.

MISCELLANEOUS VOLUMES.

A NUMBER of books bearing on problems in social economics may be grouped together here.

The Union of South Africa, with its problems, bulks so largely in the public eye just now that Miss VIOLET R. MARKHAM's interesting and thought-provoking book, *The* [illegible] Problems, in which political, racial, linguistic, social, industrial, and other matters are discussed in a restrained style but with remarkable insight. There are items of medical interest too. The Indian Ambulance Corps, which did good service in the field during the war, commemorated by a monument in Johannesburg, receives a tribute. Miners' phthisis as an industrial problem is considered. The work of the scientific laboratories at Onderstepoort, under the charge of Sir Arnold Theiler, K.C.M.G., in which, among other scientific researches, endemic diseases are studied in their relation both to animals and man, receives notice; while, of course, Dr. Livingstone's and Sir Starr Jameson's activities as explorer and administrator respectively crop up from time to time to shed a reflected glory on the profession of medicine.

Constructive Conservatism (London: The Stepney Press. 1913. Pp. 64. Price 1*s.* net), by HARRY ROBERTS, is not, as one might expect from the title, a party political pamphlet, but rather an attempt to point out the way to the fullest development—physical, mental, and moral—of the British race, not through the separation and mutual antagonism of the Syndicalists and Socialists and Liberals and Tories, but through the separation of those who care for the well-being of England and the liberty and well-being of the men, women, and children of England from those who care only for their own careers, or possessions, or logical consistency, or social prestige, or party score. To effect this he advocates the institution of an English national policy in accord with the spirit and ideals and traditions of the English people, which shall have for its object the fullest possible development—physical, mental, and moral—of every child born in England. It is neither visionary nor revolutionary. Though doubtless all will find something to dissent from in it, probably most will find much more that commands their assent. The pamphlet ought certainly to be read by all social economists.——*National Service and National Education*, by ERIC GEORGE, with an Introduction by Lord HENRY CAVENDISH-BENTINCK, M.P. (London: P. S. King and Sons. 1913. Pp. 83. Price 1*s.* net), is a very excellent little pamphlet in the main, though naturally everyone will not agree with all the details. Mr. George insists upon a point in which most people will agree with him—namely, that the proposals of the National Service League, admirable though their general principles are, fail in one important particular: that they do not propose to begin the training of citizens until the age of 18; whereas, as Mr. George rightly says, the critical age is 14 to 16, when a boy leaves school. His plan, as laid down on page 22, is that all boys should have simple physical exercises and squad drill while at school; that on leaving school at or under 16 they should spend one year at a training school for a partly military curriculum, where strict discipline should be enforced; after this they should be members of the Officers' Training Corps or of a cadet corps up to the age of 18. (Practically the same scheme is advocated in *Constructive Conservatism*, reviewed above.) After this they may, if they liked, join the regular army, the Special Reserve, or the Territorials, but training is to be compulsory up to the age of 18. The training school is to be a boarding school. The scheme is well worth the consideration of the authorities.——*A National System of Education*, by JOHN HOWARD WHITEHOUSE, M.P. (Cambridge: The University Press. 1913. Pp. 92. Price 2*s.* 6*d.* net), we learn from a prefatory note, "is issued with the general approval of the executive committee of the Liberal Education Group of the House of Commons, though they are not necessarily committed to its detailed recommendations." If the Liberal Education Group has read Mr. Whitehouse's recommendations its members will feel relieved at his statement, for his recommendations entirely upset, it seems to us, the whole educational system of the country. We are quite willing to allow that that system does need alteration, but Mr. Whitehouse goes too fast. The "additional heavy cost," which he allows will be necessary, is to be met out of the taxes; the school age is to be raised to 16, or possibly higher. As a beginning, we are to have a Royal Commission on Private Schools (Chapter VIII.), a Royal Commission on the Universities of Oxford and Cambridge (Chapter X.), and a Permanent Financial Commission of the Board of Education (Chapter IX.). As to the religious question, Mr. Whitehouse dismisses it as "a very limited and a very small question." It is no part of our duty to say whether the advocates of religious teaching are right or wrong, but they cannot and will not be dismissed in such a cursory fashion.

JOURNALS AND MAGAZINES.

Brain: a Journal of Neurology. Vol. 36. Part 1.—The first number of the new volume consists of three papers of considerable but varied interest. The first is the combined work of the Editor and Dr. E. G. Fearnsides with Dr. J. McIntosh and [illegible] the question of parasyphilis of [illegible] Wassermann reaction being the c[illegible] the paper of [illegible] true: [illegible] dition. The paper is [illegible] for it draws a definite distinction between tertiary and parasyphilitic affections of the nervous system, the former being regarded as depending upon the reaction of the hypersensitised connective tissues and blood-vessels in the nervous system, the latter as depending upon the hyperallergic reaction of the essential nerve elements and neuroglia. Thus the pathogenesis of the two conditions is the same—each being determined by the reaction of the tissues to the spirochæte or its toxins, but in the two cases the tissues reacting are different. In tertiary syphilis nervous symptoms are produced by the pressure of proliferated connective tissue on nerve elements, in parasyphilis the reaction of the nervous tissues themselves leads to their destruction. Such a view is held to explain the intractability of parasyphilitic manifestations by antisyphilitic remedies as contrasted with the cures which follow the use of anti-syphilitic remedies in tertiary syphilitic affections. The second paper is a very elaborate study of the brain of a macrocephalic epileptic by Dr. J. Wiglesworth and Dr. G. A. Watson, and in the third paper Dr. W. G. Spiller discusses the subject of myopathy, and especially the relation to this condition of such cases as those of myotonia congenita, myotonia atrophica, and true muscular hypertrophy. It will be seen that *Brain* continues to maintain the high standard which it has accustomed its readers to expect.

Æsculape for November contains several interesting articles. Mme. Dr. G. Yves-Roy discourses of centenarians in a continued article. Dr. P. Raymond describes the herbarium of Rousseau, consisting of 180 plants mounted by himself and given to Mdlle. Madeline Boz de la Tour, with extracts from his letters to that lady. Dr. E. Sicard discusses the question of euthanasia, strongly combating the plea for "merciful interposition" in suffering, and especially insisting that it is under no circumstances the part of the medical man to destroy life. Dr. Just Navarre gives interesting sketches of the medical men who attended Pascal in his last illness, dealing in this number with Noel Vallant, François Quénaud, Nicholas Brayer, Pierre Hommels, and Eusebius Renaudot. Dr. H. Douzane, an army surgeon, continues his impressions of Morocco before the protectorate. Dr. Bonnette writes of the death of Sergeant Blandan, a young hero of the Algerian army in 1842, who was wounded in the thigh, the chest, and the abdomen, and was succoured on the battlefield by an assistant surgeon named Ducros, although he had but just immobilised his own right arm, shattered by the explosive effect of a ball fired at close quarters. An excellent account of Professor Le Double, the man and his work, follows from the pen of Dr. Dubreuil-Chambardel and Dr. Faix.

The Military Surgeon.—In the number for December Major R. B. Miller, of the Medical Corps, United States Army, describes the successes and difficulties in the sanitary administration of a divisional camp (8000 men) at Texas City from March 1st to July 31st. He discusses in most useful detail latrines, latrine covers, destructors, fly-traps, and manure-burning. He was himself the sanitary officer, and finds that that unit presents the best sanitary appearance whose commander is interested in sanitation and gives it his personal attention; further, that surgeons really interested and energetic always managed to obtain good results in their regiments. Stale beer, fish, and meat make the best baits in fly-traps in his opinion, while to burn out latrine pits, which should be done daily, 5 pounds of hay per company, or 1½ gallons of oil, suffice, half a barrel of quicklime being added just before the pit is filled in. Lime inhibits the growth of bacteria, but does not reach fly larvæ. Typhoid prophylaxis was complete, and there were no typhoid cases. Major W. W. Reno again[1] draws attention to the accelerated removal of wounded off the battlefield which would be secured if his scheme for putting wheels on stretchers and harnessing the ambulance mules or horses to these, which he terms ambulance-travois. His paper is very suggestive and has good illustrations. He calculates that he can in the same time so remove six times as many wounded from the dressing stations to the ambulance as can be moved by bearers in the manner now recommended. Captain C. E. Yount, of the Medical Corps of the National Guard, notices that Mediterranean fever was first reported in the United States in 1905, but that it has quite possibly existed there, particularly amongst goatherds, for 25 years, and that it is now not infrequently met in Arizona, Texas, New Mexico, and California. He suspects the disease was carried by goats imported from Malta, and records the large number of cases which occurred in the Italian army in Tripoli in 1911–1912. It is noted that there is far more tuberculosis in the French than in the German navy, and this is ascribed to the more frequent infection of French sailors in their homes, for tubercle is a scourge in Normandy and Brittany, from which provinces France draws most of her seamen.

Dental Record.—The January issue contains a long article by J. F. Colyer on Abnormalities in the Position of the Teeth in Animals. There are close on 50 illustrations, mostly of specimens contained in the Odontological Section of the Museum of the Royal College of Surgeons of England. The author shows that many of the abnormalities met with in man are also to be seen in the lower animals. The somewhat frequent irregularity in the monkeys of complete displacement of a premolar he considers is intimately associated with the developmental position of this tooth in those animals. Reference is made to the difference in the arrangement of the teeth in species possessing long-muzzled and short-muzzled varieties, and he considers these irregularities are evidence of the greater variation of the jaw compared to the teeth.—Dr. J. Sim Wallace continues his paper on Recent Investigations of the Causation of Dental Caries, and expresses the opinion that sulphocyanate of potassium is not related to the incidence of caries. The paper also contains interesting remarks on the relation of alcohol to caries.—Mr. G. Northcroft gives an account of a Modification of the Apparatus suggested by Mr. W. W. James for the relief of mouth breathing.

British Dental Journal.—The issue for Jan. 1st has a short note on two cases of Teeth-containing Cysts, which shed a ray of light on the pathology of this type of cyst. There is also an article by Mr. R. M. Wormald, briefly summarising the present position of army dentistry in the different nations.

Jahreskurse für ärztliche Fortbildung. Munich: Lehmann. Price 18 marks per annum.—The October number contains a review on the subject of the various forms of acute meningitis by Dr. H. Schottmüller. He speaks first of the technique of lumbar puncture and emphasises its importance in the differential diagnosis, and then passes in review infective meningitis due to the pneumococcus, staphylococcus, streptococcus, meningococcus and influenza bacillus, tuberculous meningitis, and meningitis comitans. He recognises that a few more or less unquestionable cases of tuberculous meningitis have recovered. By meningitis comitans is meant a condition in which the symptoms of meningitis are present as a complication of brain abscess, sinus thrombosis, or of cortical hæmorrhage, often following otitis media, but there is no bacterial invasion of the meninges, and the lumbar puncture shows an excess of leucocytes and a little albumin, but no organisms. With reference to the treatment of the various forms of meningitis, lumbar puncture, followed, it may be, by washing out with chinosol or lysol, and the administration of a suitable serum, are mentioned with favour. Two writers next consider the subject of the mutation of bacteria, and the poisonous effects which may follow the administration of animal extracts given intravenously. Lung and liver extracts, in particular, produce such effects. A general review of recent work bearing on immunity follows. Dr. M. Mayer writes on tropical medicine, with special reference to the insect carriers of disease.—The November part is devoted to diseases of the eye, nose, and teeth. Professor Krauss discusses inflammation and other diseases of the lacrymal apparatus, and then passes on to consider the value of salvarsan in syphilitic affections of the eye, which gives better results when the front of the visual tract is diseased than when the back is at fault. Good results are also obtained in syphilitic lesions of the optic nerve, but not in interstitial keratitis. The etiology and treatment of glaucoma are also spoken of. Professor Preysing devotes his article to a description of the various signs and symptoms of disease of the pituitary gland, with illustrations, largely following the experimental work of Achsner. This differs from Cushing's well-known results in some respects; for instance, total extirpation was not always fatal. The various routes by which the gland may be removed in man are figured and described. The operation mortality is thus given: 26 patients, Hirsch route,

---

[1] The Lancet, Feb. 1st, 1913, p. 343.

11·5 per cent. died; 29 patients, Cushing route, 13·7 per cent. died; 45 patients, Schloffer route, 37·8 per cent. died; 14 patients, von Eiselsberg route, 28·5 per cent. died. The writer describes a palatine route. It will be seen that the endo-nasal approach gives better results than that by way of the ethmoidal cells. Professor Dieck discusses the dental origin of trigeminal neuralgia.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the ninth meeting of the Royal Commission on Venereal Diseases, which was held on Dec. 15th, 1913, evidence was given by Mr. J. Ernest Lane, senior surgeon of St. Mary's Hospital and of the London Lock Hospital, and a member of the Royal Commission.

Mr. Lane said that in his opinion venereal diseases are attended by just as great a mortality as tuberculosis or cancer, and although it was not possible to obtain figures to support this view, it was one which had been more or less frequently expressed by well-qualified persons. He thought that the diseases were somewhat less prevalent than 20 or 30 years ago, but on this point it was very difficult to speak with certainty; the statistics of death certified as due to syphilis did not give any idea of the prevalence of the diseases. Mr. Lane said that, although large subscriptions are given to the cause of combating other diseases, nothing has been done with regard to venereal diseases, and public money has never been expended except in carrying out the Contagious Diseases Acts. He laid stress on the necessity for improved and free hospital treatment, and said that every patient suffering from any form of venereal disease ought to be entitled to gratuitous treatment and medicine and to bacteriological and other tests. If it is desired to cure syphilis and get rid of the disease anything that would aid early diagnosis ought to be at a patient's disposal without expense to him. In any scheme for the efficient treatment of the diseases the establishment of night clinics was essential.

On the subject of notification Mr. Lane said that though he had formerly been in favour of notifying all cases of venereal disease to the sanitary authority, he had now modified his view because he was convinced that notification would deter sufferers from seeking proper advice and would lead to increased recourse to quack treatment. Dealing with the question of the education of public opinion with regard to venereal diseases, he said that in the first place the infected person must be instructed. It should be made compulsory for medical practitioners to supply to every patient suffering from venereal disease printed instructions as to the nature of his disease and as to the measures he should adopt to avoid spreading the trouble; copies of these instructions should be supplied gratuitously to the doctors. Secondly, he would suggest that all institutions where there are a large number of employees or institutions such as colleges and universities ought to have some course of lectures explaining the dangers of venereal disease. It was also of the greatest importance that the standard of knowledge of these diseases in the medical profession should be raised; in the past the teaching given in the medical schools was very inadequate, but steps were now being taken in some of the more important hospitals which should lead to an improvement in this respect.

Mr. Lane gave some statistics of the work done at the London Lock Hospital. He showed that during the last 30 years there has been a remarkable diminution in the number of prostitutes treated at the Female Hospital; at the present time the majority of the female patients were very young girls, and 13 per cent. of the patients were married women. All the cases in the children's wards and the greater part of the married women were examples of innocent syphilis. In the Male Hospital the new out-patient department opened in 1911 had proved most satisfactory, and the number of attendances was increasing; a new in-patient department was opened in November last with three wards perfectly fitted with all modern accommodation for 40 patients.

At the tenth meeting, held on Dec. 19th, Dr. T. H. C. Stevenson, Superintendent of Statistics to the Registrar-General of England and Wales, attended and gave evidence supplementing that which he gave at the first meeting. Dr. Stevenson said that though the statistics tabulated from death registers by the Registrar-General cannot be claimed to afford any measure of the absolute amount of mortality from venereal disease, they do throw light in varying degree upon its relative amount, whether the comparison made be historical, geographical, or social. Looking at the matter from the historical point of view, the curve of mortality from syphilis in England and Wales shows a very large and rapid rise between 1850 and 1868, followed by a period of fairly sustained elevation till about 1886; this is succeeded by ten years of rapid fall, and the fall has continued, though it has become less rapid since 1896.

Dr. Stevenson was of opinion that the fall recorded in the last 30 years represented a genuine decrease in the mortality from the disease; he gave several reasons in support of this view, and referred also to the large contemporaneous fall in the curves showing prevalence of syphilis in the army and navy. To illustrate the incidence of syphilis and diseases resulting from it on various occupational and social classes, tables had been prepared in which the male population was graded according to occupation into five main groups and three additional groups (textile workers, miners, and agricultural labourers) representing the three largest single industries. Of the five main groups, the first consisted of the upper and middle classes, and was sufficiently comprehensive to include clerks and insurance agents; the fifth group represented unskilled labour. The most striking feature of the tables was the uniformly low mortality of textile operatives, miners, and agricultural labourers, the last group especially yielding very low rates. Of the five main groups the highest mortality was found in Group 5. The mortality from syphilis was lowest in Group 1, but the mortality recorded against it from the parasyphilitic diseases was high, and for locomotor ataxy the rate was higher than that of any of the other groups.

Taking all the circumstances into consideration Dr. Stevenson conjectured that syphilis is most prevalent amongst the highest and lowest of the five social classes he dealt with, and that the three great industries of textile manufacture, mining, and agriculture are almost certainly exceptionally free from the disease. With regard to the geographical distribution of the diseases the tables furnished by Dr. Stevenson indicated that the prevalence in the large towns was much greater than in the rural and small urban districts.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bologna:* Dr. Giuseppe Ficai has been recognised as *privat-docent* of Hygiene.—*Bonn:* Dr. R. O Neumann, professor in Giessen, has been appointed to the chair of Hygiene, in succession to Dr. Kruse.—*Florence:* Dr. Riccardo Chiappella has been recognised as *privat-docent* of Hygiene and Sanitary Police.—*Freiburg:* Dr. K. Ziegler, of Breslau, has been appointed Extraordinary Professor of Medicine.—*Gottingen:* Dr. W. H. Schultze, *privat-docent* of pathological anatomy, has been granted the title of Professor.—*Greifswald:* Dr. P. Römer, extraordinary professor in Marburg, has been appointed to the chair of Hygiene, in succession to Dr. Löffler.—*Harvard:* Dr. Reid Hunt has been appointed to the chair of Pharmacology.—*Heidelberg:* Dr. Hans Petersen has been recognised as *privat-docent* of Anatomy.—*Naples:* Dr. Domenico Enca and Dr. Annibale Taliercio have been recognised as *privat-docenten* of Midwifery and Gynæcology.—*New York (University and Bellevue Hospital Medical College):* Dr. William B. Tremble, lecturer, has been promoted to the Professorship of Dermatology and Syphiligraphy.—*Padua:* Dr. Antonio Berti has been recognised as *privat-docent* of Medical Pathology.—*Parma:* Dr. Aldo Tedeschi has been recognised as *privat-docent* of Hygiene.—*Pisa:* Dr. Renato Pirani-Coen [illegible] of Midwifery and Gynæcoc[illegible] been appointed Professor [illegible] Marras has been recognised as *privat-docent* of Hygiene.—*Sienna:* Dr. Mario Chiarugi has been recognised as *privat-docent* of Surgery and Operative Medicine.—*Toronto:* Dr. Fred Marlow has been appointed Adjunct Professor of Gynæcology.

PARKE, DAVIS & Co.'s PAGE

LETTERS TO MEDICAL MEN

1. ON THE NEW METHOD OF TREATING INFECTIOUS DISEASES.

The new method

DEAR SIR,—You will observe that the heading of this letter speaks not of "a" new method, but of "the" new method of treating infectious diseases. The use of the definite article is based on the assumption that there has been introduced into medicine a new, definite, and (within certain limits) specific method for the treatment of diseases of microbic origin. Whether such use is justified will subsequently appear. The idea of "newness" is relative, and its application in any given circumstances must be carefully circumscribed. We have it on the best authority that "there is nothing new under the sun," and very likely many medical men will tell you there is nothing new about Phylacogen, that it is simply mixed vaccine "writ large." This, of course, is not the case, since the Phylacogens belong to a class of preparations very different from vaccines. Some other day we shall probably discuss the relationship between the two, but such discussion is outside the scope of the *present letter*.

Its Origin

The credit for the discovery of the idea that ultimately crystallised as Phylacogen belongs to an American medical man, Dr. A. F. Schafer, of Bakersfield, California, Dr. Schafer had for some considerable time been making use of a new form of bacterial derivative in the treatment of acute and chronic infections, and in due course he announced his discovery to the profession through the San Joaquin Medical Society, at Fresno, California, in October, 1910. Later, on January 14th, 1911, the subject was further elucidated before the San Francisco Medical Society, and on April 15th of the same year a paper by Schafer on his method of treatment was published in the *Therapeutic Gazette*, the well-known medical monthly, edited by Dr. Hobart Amory Hare, of Philadelphia.

Theory of its application

The principle upon which the use of Phylacogens is based *is, briefly, the* theory of multiple infections. Dr. Schafer's belief, founded on large clinical experience, supplemented by exhaustive *scientific* research, is that all infections are mixed infections; *that except* in rare instances there is no such thing *as an* infection by a single species of micro-organism; *that* while one species may predominate, the pathological process engendered by it is accelerated and *intensified by the* presence of organisms of other species; in other words, that in the case of an infectious disease the symptoms are due not only to the effects *of the* specific infecting organism, but to the influence of other organisms whose pathogenic rôle is not insignificant, and which must *be reckoned* with in any successful scheme of therapeutics.

The name Phylacogen.

The term Phylacogen *has* been coined to distinguish the several bacterial derivatives introduced by Schafer. Each specific Phylacogen is further identified by *prefixing* the name of the pathological condition in which it is indicated, as, for example, Rheumatism Phylacogen, Pneumonia Phylacogen, &c. The word Phylacogen is derived from two Greek roots, and it means "*phylaxin producer*," phylaxin being the name applied by Hankin to a defensive proteid *found in animals* that have acquired an artificial immunity to a given infectious disease.

Preparation

Phylacogens are made from a large variety of pathogenic bacteria, including Staphylococci, Streptococci, B. Typhosus, B. Coli Communis, B. Pyocyaneus, B. Diphtheriæ, D. Pneumoniæ. These bacteria are grown in artificial media, the cultures being incubated at 37° C. for 72 hours or longer. Thereafter, the organisms are killed, a preservative consisting of 0·5 per cent. of phenol is added, and the fluid is filtered through porcelain. The filtrate therefore contains sterile aqueous solutions of such metabolic derivatives as are generated by the bacteria in their growth. The mixed filtrate is known as *the basic Phylacogen or "Mixed Infection Phylacogen."* This is a true polyvalent preparation, since the organisms are not from one strain only of a *given* species, but from cultures made at frequent intervals and from a variety of sources.

Specific varieties

Each specific Phylacogen is prepared by modifying the basic material by the addition of a *certain proportion* of filtrate obtained by growing the organism considered to be predominant in the *pathological* condition to be treated—for instance, in the preparation of Rheumatism Phylacogen the streptococcus rheumaticus (Poynton and Paine) is cultivated, and the filtrate obtained therefrom is added *to* the Mixed Infection Phylacogen. A *like method* is employed in the preparation of other specific Phylacogens, such as Pneumonia, Gonorrhœa, Erysipelas, &c.

Clinical Tests

Before we undertook the manufacture of Phylacogens we made a searching investigation of all the circumstances surrounding the work in California. Several competent attachés of our Scientific Department personally visited hospitals in which cases were treated, and witnessed the unique results obtained. Not content with this, our Department of Experimental Medicine, with which are associated upwards of two thousand medical men of very high standing in America, carried *on for* more than a year a series of searching clinical tests. A vast mass of work was done in the laboratory, on animals, in the hospitals, and at the bedside. It is literally true that many hundreds of reputable physicians have administered thousands of doses of the Phylacogens, and a critical survey of the results obtained has convinced us that these remedies possess great therapeutic power.

Introduction to Medicine

Having thoroughly *investigated* the claims made in favour of the new treatment, and having satisfied ourselves that *these claims* were justified, we *introduced Phylacogens to* the medical profession in America on February 8th, 1912. They were introduced experimentally in Great Britain in October of the same year, and after we had received many exceedingly favourable reports from English and Scottish doctors, we offered them to the British Medical Profession on February 22nd, 1913. Since that time we have received a very large number of clinical reports, and the results have been exceedingly satisfactory. Some of these reports have been printed in a new edition of "Phylacogen Therapy," which has just been issued, and if you are interested in the subject, please write us for a copy and it will be sent you immediately.

Beak Street, Regent Street, London, W.

THE LANCET.

LONDON: SATURDAY, JANUARY 10, 1914.

Vaccines from the Standpoint of the Physician.

The lapse of time puts new discoveries and new developments in all branches of knowledge into their true perspective in the scheme of things known and accepted. The impetus which scientific research in pathology, bacteriology, and pharmacology has given to the search for new remedies and methods of treatment affords one of the most striking features of the medicine of the present day. That these methods are too often employed unscientifically by those engaged in the practice of medicine not infrequently brings discredit upon valuable methods, so that the perfervid enthusiasm with which they are at first greeted gives place to disappointment and even undeserved neglect. Practical medicine is in a hurry for new and more effective remedies, and the maxim to prove all things is forgotten in the desire to advance. New remedies should be used critically, and statements made about them should be tested in the light of experience. In these matters the medical profession owes an important duty to the public. Owing to the wide and sometimes too early publicity given by the daily press to novelties in medicine, hopes are raised only to be doomed to disappointment, and the distrust and dislike of fresh methods, which were characteristic of former generations, have given place to a too avid demand for trial of the so-called latest advances of medical science. For these reasons, among others, discussions such as that announced to take place at the Section of Medicine of the Royal Society of Medicine on Tuesday, Jan. 27th, on the subject of Vaccines from the Standpoint of the Physician, serve a very useful purpose, and we look forward with great interest to the reports of this particular discussion.

Although, as its name suggests, vaccine-therapy is by no means new in principle, introduced as it was by Jenner, and further developed by Pasteur and Koch, yet its wider applications are comparatively recent, and are due in no small measure to the work of Sir Almroth Wright and his co-workers and pupils. They have endeavoured to work out the general principles underlying the use of vaccines, to elucidate the manner of their action, and to explain their effects in terms of the general theory of immunity to bacterial agencies. Essential to advance as these aspects of the problem are, it must not be forgotten that they are in a sense theoretical, since they depend upon the assumption of certain general reactions, which, though they may be established for certain bacterial agencies, must not yet be regarded as generalisations. The standpoint of the practising physician must be considerably utilitarian. He requires to know in what infections vaccines are of proved value, in what forms of those infections and at what stages they are best employed, what doses give the best and most lasting results, at what intervals they shall be given, and for how long continued. Questions such as these will, we venture to hope, occupy a prominent place in the forthcoming discussion. It may probably be taken as generally accepted that vaccine-therapy affords a noteworthy addition to our means of treatment of diseases produced by bacterial agencies, but owing to the many difficulties involved and the large amount of work still necessary to fill up gaps in our knowledge, the time is perhaps not yet ripe for the discussion of its comparative value in regard to other methods. From the theoretical standpoint it would appear to be the ideal form of treatment, since it seems to be a direct appeal to the natural processes of immunity. But the history of antitoxic serums shows how much we should be on our guard against generalisations from particular cases, since, great as their value undoubtedly is in infections where soluble toxins are the chief factor in the production of the disease manifestations, their use is so far strictly limited to these conditions and by no means of the general application which was originally hoped for. Moreover, vaccines as at present prepared must of necessity be crude and of highly complex and even variable composition, so that the constituent which is actually effective may be accompanied by numerous other substances derived from the bacterial protoplasm or from the culture medium, which may hinder or oppose its action or produce other undesired effects. The history of the use of tuberculin, the vaccine which has probably so far been more widely used than any other, illustrates this in the most marked manner. The long and ever-increasing list of modifications of tuberculin affords the best evidence of the continued search for purer and more constant, if not simpler, forms of tubercle vaccine.

Another point of practical interest to which we hope some attention may be given is the determination and authoritative statement of the different methods of vaccine treatment to be applied to local infections and to acute and chronic general infections respectively. Sir Almroth Wright, in explaining the actions of vaccines in disease, is careful to differentiate between their local and their general actions, and to discuss the relation of these to dosage and to the nature of the bacterial bodies and to the cells and fluids of the infected person. The practical application of these matters is one of great importance. A further aspect of the use of vaccines of which the physician is bound to take cognizance is that which is so admirably illustrated by the report of Sir ALMROTH WRIGHT and his collaborators, Dr. W. PARRY MORGAN, Dr. L. COLEBROOK, and Dr. R. W. DODGSON, on Prophylactic Inoculation against Pneumococcus Infections, published in last week's and in this present issue of THE LANCET. As a study of scientific method applied to the elucidation of a difficult problem in connexion with vaccine treatment, and as an illustration of the laborious character of such work, we can commend this report to our readers. Its interest, however, is enhanced by the promise which it holds out of a truly specific method of dealing with pneumococcus infections both prophylactically and therapeutically. It seems difficult to resist the conclusion that the pneumococcus vaccines employed by these observers lessened the incidence and the mortality of pneumonia and other conditions produced by the pneumococcus among large collections of natives, who were highly susceptible to its activity and under conditions favourable to the spread of infection. For scientific reasons Sir ALMROTH WRIGHT and his collaborators confined themselves to the study of the prophylactic effects of these vaccines, but a consideration of these statistics would seem to indicate that their use favourably influenced the progress of cases inoculated during the incubation period and early in the disease, so that it is not too much to hope that further work on the same lines may establish the therapeutic value of these vaccines in pneumococcus infections. This report forms an excellent introduction to the forthcoming discussion, since it illustrates in such a clear manner the nature of the problems involved in vaccine-therapy, the difficulties to be contended with, and the practical methods of dealing with them. One of the difficulties of the physician in the application of vaccine-therapy is the practical impossibility of controlling the effects of his treatment by means of the opsonic index or the other quantitative immunity reactions which are employed under laboratory conditions. It may be hoped, therefore, that a further useful outcome of the discussion will be to set up some general scheme for the observation and record of cases submitted to vaccine treatment, so as to afford a more uniform basis for comparison of results, and for the compilation of trustworthy statistics by enabling the results of isolated groups of cases observed by different workers to be summed together and raised to the dignity of a mass-experiment. Lastly, we may also express the hope that the discussion at the Royal Society of Medicine will serve to emphasise the fact that vaccines, being potent agents capable of doing harm when injudiciously employed, should be given only with a sense of responsibility in conditions in which their use is definitely indicated and confirmed by bacteriological evidence.

The Asylum Medical Service.

RATHER more than 12 months ago there appeared in the columns of THE LANCET some letters calling attention to the very unsatisfactory position of assistant medical officers in public asylums for the insane in this country. The note of discontent sounded in these letters has since then found an echo throughout the asylum service, which, by its vigorous resonance, gives convincing evidence of the reality of the grievances that our correspondents sought to ventilate. But we live in times when, as experience should assuredly have taught the medical profession, it is of little use to prove the justice of your cause unless you are in a position to drive home your proofs by arguments of the more practical sort that appeal to public bodies and administrative departments. This fact, we are glad to observe, has been fully recognised by the assistant medical officers. Instead of being content with a simple statement of the disabilities under which they labour, they have very wisely taken steps to organise themselves into an association for the removal of these disabilities and for the protection of their professional interests. This movement was inaugurated at a meeting of the assistant medical officers of the public asylums in the Midlands, held at Birmingham on Nov. 18th, when a provisional committee was appointed and a guarantee fund was raised; and since that date similar action has been taken by the assistant medical officers in the North of England and North Wales at a meeting at Manchester on Dec. 3rd, by their colleagues in the West of England and South Wales, who met at Bristol on Dec. 4th, and by the assistant medical officers of the asylums in the metropolitan district at a meeting in London on Dec. 5th. These proceedings are preliminary to the formation of a general association of officers of this rank in the asylum service of England and Wales.

The conditions which have given rise to this widespread spirit of dissatisfaction are not, of course, altogether of recent growth, but the acute consciousness of their injustice and the resolute determination to alter them may doubtless be attributed in large part to influences which have become increasingly operative within the last few years. Men who by temperament or circumstances are tempted to enter public services can now find many openings offering higher remuneration and more brilliant prospects than can be looked for even in asylums governed by the most progressive committees; the very newness of these openings, ensuring as it does a relatively rapid advancement to positions in which there is larger responsibility and wider scope for initiative, gives them a manifest advantage over an old-established service where promotion is necessarily slow and certain. The multiplication of these more immediately attractive careers, in connexion with the public health service, the inspection of school children, the control of tuberculosis, and so forth, has by contrast brought out more clearly the unsatisfactory features of the asylum service. And when criticism is turned in this direction it finds no lack of suitable material to work on. As Mr. F. J. STUART pointed out in his speech to the assistant medical officers at the meeting in London last month, it is impossible to retain the best men in a service where all but the highest posts are inadequately paid, where promotion to such posts is more dependent on local accident and extrinsic influences than on scientific distinction, and where, moreover, for officers below the rank of superintendent, the conditions of service are in certain respects derogatory to personal and professional dignity. During the past year this question has engaged the attention of the Medico-Psychological Association, and a committee of that body has instituted inquiries into the conditions of asylum work and the status of asylum assistants in other countries. The interim report presented by the committee was published in the *Journal of Mental Science* for last October, and the facts which it sets out are amply sufficient to explain why assistant medical officers in English asylums are dissatisfied with their present position. The circumstances are, of course, very different in different countries, and a comparison of the asylum systems with one another and with the English system is therefore somewhat difficult; but so far as concerns this particular question of the status of assistant medical officers, the facts must certainly warrant the conclusion that, as a general rule, the junior physicians on the staff of a French or German asylum have a wider field of professional activity and enjoy a larger measure of personal independence than do their colleagues in English mental hospitals. Interest in scientific work meets with more direct encouragement, and greater facilities for original research and for special psychiatric study exist. In many countries the senior medical officers have a considerable degree of autonomous responsibility in the treatment of their patients and in the general management of the sections under their charge; and by the general permission to marry and by the liberal provision of suitable married quarters some of the most irksome of the social restrictions that weigh so heavily on assistant medical officers in English asylums are obviated. It is, of course, more than probable that there is another side to this picture, and that the physicians in continental asylums have grievances of their own; but even if this be the case, it obviously cannot constitute any reason why the better features of the asylum systems of other countries should not be adopted and combined with whatever special advantages are to be found in our own institutions. This, it is to be presumed, is one of the immediate aims to which the proposed Association of Assistant Medical Officers will direct its energies, and the action of the Medico-Psychological Association indicates very clearly that in this matter the acknowledged leaders of English alienism are in full sympathy with their junior colleagues. There can be no question that the medical profession outside the psychiatric specialty will be equally ready to adopt the same attitude and to support any well-considered and temperate action calculated to remove the conditions which at present render the asylum service one of the least attractive careers open to the young physician. And there are encouraging signs that the more enlightened public bodies are also fully alive to the urgency of this problem, and that they will welcome proposals of a practicable character tending to bring about a better organisation of the medical care of the insane. The difficulties which are being encountered in finding applicants for the junior applicants in many asylums can hardly fail, indeed, to force the matter on the attention of local authorities.

The very fact that so many conditions are coöperating to form an atmosphere favourable to reform imposes a grave responsibility on those who may have any share in framing the policy of the medical profession in regard to this question. The problem goes deeper than the personal grievances of the assistant medical officers in our asylums; it reaches down to the very foundations of the scientific position of psychiatry and its relation to the rest of medicine. These larger issues we do not now discuss, but they will have to be fully examined and the practical difficulties which they present will have to be met before a satisfactory solution can be found for the questions which are agitating the asylum service. As a preliminary the comparison with conditions which hold good in other countries may again be helpful. It may suggest, for instance, that some of the advantages which are enjoyed by asylum officers abroad are due in large measure to the fact that in continental countries psychiatry occupies a less isolated position and is kept in closer contact with the main stream of medical science than is, generally speaking, the case in England. And, as bearing on this point, it may be worth inquiring how far the more favourable position of psychiatry in these countries is due to the existence of a State service with its wider facilities for interchange between the various asylums, its freedom from the control of petty local interests, and its larger field for scientific ambition. Of course, such a system has its drawbacks as well as its merits, but in the particular case of the asylum service the worst of these drawbacks exist already and are probably inevitable under any system, so that the strongest arguments against State organisation as applied to medicine are irrelevant in this instance. The whole question, however, is one which calls for careful and detailed discussion, and it is, therefore, rather as a tentative suggestion than as a considered opinion that the solution of a State service is put forward as a possible way of bettering the professional and social status of asylum medical officers and of advancing the interests of psychiatry.

The Sterilisation of Milk and Allied Questions.

CONSIDERABLE prominence has been given in the press during the last fortnight to the question of whether milk should be sterilised. This term, it may be observed, has been much misused in regard to milk. Pasteurisation consists usually in heating the milk to a temperature of 150°–160°F. for 20 or 30 minutes; scalding or boiling generally means heating near to boiling point; while sterilising, if strictly carried out, as is the case in a few special processes of limited use, is done by exposing the milk to a temperature of 212°F. for 40 minutes. It is usually assumed that under the first process there is no important change in the composition of the milk, but that there occurs a partial destruction of bacteria, chiefly those of the lactic and coli group. Under the second process a more advanced sterilisation is effected, with some decided changes in the composition of the milk; and under the third, complete sterilisation for all practical purposes, including the destruction of the tubercle bacillus, is attained. The last, however, is claimed to alter the dietetic properties of the milk somewhat further than mere boiling, at least when employed for infant feeding.

In the discussions to which we refer, however, the term "sterilisation" has been applied practically to all processes of heating milk, and has related to the effect of heat both on living organisms and on the ferments and the supposed "vital principles" of milk, on which much stress is laid by Mr. EDMUND OWEN in the letter which will be found in another column. They originated with an account published in the *Times* of Dec. 29th, 1913, of the production of clean raw milk, immediately refrigerated, at Mr. ROBERT MOND'S experimental farm near Sevenoaks, and its use at the Infants Hospital, Vincent-square, Westminster. Mr. MOND is reported to have concluded, from observations made at the latter institution, that children fed from birth on sterilised or condensed milk are habitually weak and ill-nourished and prone to tuberculosis. Similar statements have from time to time been made, sometimes by physicians with special opportunities of observing the health of infants of the well-to-do class who are brought up by hand. But it is well known that they are by no means supported by the experience of the large municipal milk depôts, clinics, and analogous places where hand-feeding is systematically undertaken on a large scale. In these establishments care is usually taken to obtain milk of good quality and free from infection, but almost invariably it is pasteurised or boiled before being consumed, while in the milk depôt at Leicester dried milk, which has presumably been thoroughly devitalised (to use a current expression), has been exclusively used for years. The consideration that infantile scurvy or scurvy-rickets may, though rarely, result from the treating of the milk is usually taken into account, and the concurrent use of lemon or orange juice recommended as a preventive; but with this reservation the results obtained and published certainly seem to prove that boiled or pasteurised milk is capable of affording the essential nourishment of infants and that infants thrive on it.

Some of the data available on this subject, principally from foreign sources, were collected two years ago by Dr. J. E. LANE-CLAYPON, and issued in pamphlet form by the Local Government Board. They showed in the case of man and the lower animals alike that for the young of a given species there is an undoubted superiority—probably attributable to the protein constituent—in milk derived from animals of that species over milk obtained from other species, whether sterilised or not. Such differences as could be shown between the results of sterilised and unsterilised cow's milk when given to infants were of a very minor order, not to be compared with those which obtained between cow's milk and human milk. The criticism may be made that the infants which get fed through the agency of milk depôts and clinics soon pass out of observation when they cease to be infants, and their after-history, in the matter of rickets, tuberculosis, and other ailments, is not fully ascertained. But this deficiency in evidence is not proof that they have been harmed by the heating process applied to the milk. Any new facts which can be obtained in this direction will be of great value and will deserve and receive careful study, but it will be necessary for fresh observations to be exact, prolonged, and on a scale of considerable magnitude if they are to produce the conviction that to submit cows' milk to sterilisation before giving it to the infant is to create a substantial danger to the infant's health. Mr. MOND also considers the risk run by the consumption of milk from tuberculous cows to be greatly over-estimated, and bases this on his own escape from the disease after drinking such milk, and on the argument that children fed with milk from tuberculous cows have not developed tuberculosis. An argument thus presented, however, must be somewhat futile, even on the assumption that in each case the observations have been maintained sufficiently long to be of practical value. It is no more to be expected that every child who takes a dose of tubercle bacilli in its milk should contract clinically recognisable tuberculosis than that every child who comes into close contact with an advanced case of human phthisis will do so. The proportion of town milk in which tubercle bacilli can be found is so large that on this conception of its virulence we should soon have no child population at all. The facts remain that tuberculosis of childhood is widely and seriously prevalent, and that there is a mass of research, including the invaluable investigations of the recent Royal Commission on Human and Animal Tuberculosis, which establishes the conclusion that a large proportion of the cases of tuberculosis occurring in childhood in this country are due to tuberculous infection of bovine origin—in other words, to tuberculous milk.

The risk of tuberculosis, together with the results of other infections and contaminations to which milk under present commercial conditions is liable, has to be set against the suggestion of risk, such as it is, from "sterilisation" in some form. Present knowledge seems to require that an affirmative answer should be given to the parents who have no reliable guarantee that the infant's milk comes from healthy cows and is otherwise properly treated, and who ask whether they had better boil it or at least subject it to thorough pasteurisation. Apart from the special question of infant feeding, indeed, the same answer must be given as regards the usual domestic supplies of milk. It ought not, however, to be necessary, and with the habitual preference shown for raw milk in this country the advice is not likely to be generally followed. For this reason we have strongly insisted upon the importance of the general revision and consolidation of the laws relating to the milk-supply which has so long been promised, together with the vigorous local action for the suppression of bovine tuberculosis, for which it is understood that the proposed legislation will provide. The suggestion has been made that, as the Government has so long delayed measures to protect the milk-supply at its source and in its distribution, the milk traders should themselves reassure the public by pasteurising all their milk in bulk before it is distributed; and several large firms, we believe, already adopt this practice. Its sufficiency, however, as a protection to the public is open to considerable doubt. The destruction of infective bacteria, if attained, is a clear gain. But unless sterilised or pasteurised milk is at once received in sterile receptacles, and there kept until used, other and substantial dangers may arise. The ordinary methods in which milk is conveyed, distributed, and stored in this country are quite unsuited for sterilised or even pasteurised milk. And it is noteworthy that in America, where pasteurisation in bulk is more usual than it is here, health authorities are energetically demanding that receptacles containing pasteurised milk should be labelled as to temperature and time of pasteurisation, and that commercial pasteurisation should be subject to rigid regulation and supervision.

KING'S COLLEGE HOSPITAL.—In their latest report the committee of the King's College Hospital Removal Fund, of which Lord Hambledon is chairman, announce that the contributions to the fund during the year ending August 31st, 1913, amounted to £24,121, not including £9438 promised but at present unpaid. Since the commencement of the appeal the committee have received a total sum of £382,114, of which £48,000 have been contributed by King Edward's Hospital Fund. In order to extinguish the debt a further sum of £100,000 is still needed.

Annotations.

"Ne quid nimis."

THE MOVEMENTS OF THE LARGE INTESTINE.

To the philosopher of the future, as he looks back upon the progress which has been made during the last few years in the study of the intestinal movements, there will be presented the strange spectacle of the growth of two schools of thought which, though working in apparent harmony, are yet as different as can well be imagined. The past year has seen the rise, and the very wide acceptance, of a doctrine of mechanical obstructions to the normal passage of the intestinal contents; it has also marked the free use of an eponymous nomenclature which has very little merit. That giant Vesalius has but one meagre and inconstant foramen in the cranial wall named after him, and even this, in these days of terminological reform, is like to be swept away; those with any love for the traditions of anatomy must therefore regard with horror the naming (however ephemeral the terminology is likely to be) of chance peritoneal bands and intestinal moorings after this one and that. We would not be so pessimistic as to look on these things as long-lived blots on anatomical terminology; but we would make protest against their coining. With the mechanical view in mind the alimentary canal has proved a happy hunting ground; a bend in the tube, a mechanical disadvantage, an obstructing band, an adhesion—all have been eagerly sought out, and a new terminology, mostly eponymous, has been thrust into the literature. Meanwhile, and more quietly, other work upon the passage of food along the alimentary canal has been carried out, and things only guessed at before have been patiently watched by means of the X rays. We have now a very complete knowledge of the movements which urge the food-mass onwards, and more than a guess as to the nature of the impulses which regulate these movements. In recent papers by Hertz and Newton[1] it is made abundantly clear that the ileum possesses the terminal sphincter which was claimed by Professor Keith, as an anatomist, more than 10 years ago; and further that this sphincter governs (as Keith suggested) the flow of contents from ileum to cæcum. It is now demonstrated that this sphincter is regulated by impulses connected with the passage of food into the stomach—the gastro-iliac reflex. Normal iliac stasis is therefore to be regarded as the outcome of this regulating mechanism; abnormal iliac stasis seems clearly due to some defect of this mechanism. Again, after the cæcum and colon have become filled by the passage of intestinal contents through the ileo-cæcal valve, movements of the large intestine are apparently produced by the stimulus of the entry of food into the stomach—the gastro-colic reflex—which in most individuals results in defæcation after breakfast, although the desire to defæcate may also be manifested after other meals. A theory makes a very powerful appeal, and the clinical support which it receives is undoubtedly strong; but the risk is lest it should be regarded as the whole story. Its apparent mechanical simplicity should be in itself a warning that it is not likely to be the complete explanation of what is almost certainly a subtle vital process. The mechanical disabilities which intestinal movements are able to overcome, rather than the ready impediment of intestinal contents by bends, or twists, or turns, is the fact which strikes the observer when studying the intestinal canals of different vertebrate types. On the other hand, common experience compels a belief in some gastro-colic reflex—a reflex which may be abnormally sensitive in conditions of so-called nervous or lienteric diarrhœa, while the detection of the vital rôle of the ileo-colic sphincter is a remarkable vindication of the findings of the anatomist. We are, perhaps, too near to the period of the actual discussion to survey opposing views in their proper perspective, and there lies behind them more than mere academic discussion. To the questions—Is intestinal stasis a complaint which falls within the province of the surgeon or of the physician? Should we attempt operative interference with the alimentary canal? or Should we attempt to re-educate a neuro-muscular reflex, which from some cause or other has fallen below its normal activity?—no general answer can yet be given.

---

ANTS AS TRANSMITTERS OF TROPICAL DISEASE.

No suspicion until lately has arisen that the industrious ant might upon occasion act as the transmitting agent of infection to man. It was known that some species, such as the white ant, had very destructive tendencies in certain parts of the tropics, and that the bites of some large tropical ants caused a good deal of general disturbance, being attended with faintness and shivering and sometimes with temporary paralysis. It was also known that some savage races used the dried bodies of ants, beaten into a paste, as an arrow poison, but it is only of late that suggestion has been made that this insect might convey pathogenic bacteria to man. The ant is commonly found in and around the dwellings of people residing in the tropics. It is, indeed, a matter of difficulty to keep this insect away from foodstuffs in such houses, and it is equally difficult to keep the ant away from human dejecta when these are not properly disposed of. So that it cannot be doubted that the ant has the opportunity of carrying from infected excreta the specific organisms of disease to the food stored in human dwellings. Not long ago one writer drew attention to the possibility of the ant spreading anthrax. In 1908 Dr. Andrew Balfour, then at Khartoum, in his "Review of Recent Advances in Tropical Medicine," discussed the suggestion that ants might be to blame for carrying cholera infection from contaminated fæcal matter to human food and drink. His experience was that at Khartoum ants were more in evidence than flies, and that from their crawling habits and scavenging propensities they could play a considerable part in the conveyance of cholera and similar infections. Little or no experimental work, however, had been done to obtain proof that ants were capable of transmitting diseases to man; but in 1912 Dr. L. B. Bates, bacteriologist to Ancon Hospital in the Panama Canal Zone, undertook a series of experiments with the view of putting to the test whether or not the ant acted as a transmitting agent of such infections as enteric fever and bacillary dysentery. His results were published lately in the Proceedings of the Canal Zone Medical Association, Vol. V., Part I. His investigations were carried out with the large yellow ants which are found in and around the houses in the Canal Zone. He fed a number of these insects on bread soaked with cultures of B. typhosus for five days, killing and examining some of them at certain intervals, but in no instance was he able to recover the typhoid bacillus from the intestines of the ants. The experiment was carefully repeated with like negative results. He then tried to determine if the ant could carry the specific organisms on its legs or body, in a purely mechanical way, to human food. A number of the insects were dropped into a broth culture of B. typhosus and allowed afterwards to crawl out and walk over Petri dishes, the bottoms of which were covered with filter paper, at varying intervals up to 24 hours; after that they were placed on the media in Endo plates. The typhoid bacillus was easily found in every instance. This experiment was repeated several times, and in the majority of cases positive results were obtained. It is known that the body of the ant contains a certain amount of formic acid. Dr. Bates infers, therefore, that under such circumstances it would be almost impossible that any typhoid bacillus could survive for any length of time in the intestinal canal of the ant. He concludes that the ant under certain conditions is capable of becoming an active agent in the transmission of enteric fever or bacillary dysentery to man, but only in a mechanical way. The same is almost certainly true as regards cholera. It would be of advantage if further experimental work in this direction could be carried out.

FRACTURE OF THE PELVIS IN A CHILD.

FRACTURE of the pelvis in childhood is rare because of the smallness and elasticity of the bones and the suppleness afforded by the symphyseal and epiphyseal buffers. In the "International Encyclopædia of Surgery" Packard says: "Fracture of the pelvis is almost unknown in children. The youngest patient I remember to have treated was 16 years old." In the *New York Medical Journal* of Nov. 5th, 1913, Dr. P. G. Skillern has reported the following case. A boy, aged 7, was taken to hospital. While at play on the previous day he was struck by an empty lime box over the pubic region. Examination revealed an ecchymosis between the anterior superior iliac spines and the symphysis pubis and tenderness over the ossa pubis. There were no signs of injury to the bladder, and the child could walk without difficulty. Bimanual recto-abdominal palpation, in which the pubic arch was sandwiched between the examining hands, again elicited wincing and tenderness, but no unevenness of the bones, crepitus, or preternatural mobility. There was a small hæmatoma in the space of Retzius. A skiagram showed bilateral symmetrical oblique lines involving the bodies of the pubic bones, each starting at the upper part of the symphysis and extending downwards and outwards to the margin of the thyroid foramen 1·5 cm. below the pubic crest. On the right side the fracture line passed across the lower part of the thyroid foramen to involve the body of the ischium just above its junction with the tuberosity. On the left side the ischium was uninvolved. The child was placed on a fracture bed. These lines of fracture were in keeping with the following description by Packard: "When a crushing force is brought to bear on the whole pelvis the bone may give way at two or three different points. One or the other side may be specially acted upon. In any case, however, the pubis would seem to yield first in its horizontal ramus, when there must be a fracture also somewhere between the symphysis pubis and the tuber ischii." In the present case the injury stopped short of crushing and displacing the bones. The absence of subjective symptoms was due to the subperiosteal nature of the fracture, there being even not enough displacement to involve the bladder. Perhaps it escaped because it is chiefly an abdominal organ in childhood. But for the ecchymoses and the wincing on examination arousing suspicion sufficient to resort to skiagraphy the fracture would have escaped detection.

METAPLASTIC BONE AND MARROW FORMATION IN VESSEL WALLS.

IN the *Cleveland Medical Journal* for November, 1913, Dr. H. O. Ruh has published an important paper on a subject which has not received from pathologists the attention it deserves—*metaplastic* bone for [illegible] has recently [illegible] ification and ossification in unusual situations, especially in arteries and veins. Dr. Ruh reports the following case. A woman, aged 58 years, was admitted into hospital suffering from dyspnœa and swelling of the lower limbs. At the age of 30 years she had an attack of rheumatism, from which she recovered without cardiac symptoms, but during the last eight years she had suffered from cardiac distress. On examination mitral regurgitation and obstruction were found with failure of compensation. The urine contained albumin and a few epithelial cells. She died soon after admission. At the necropsy about 1000 c.c. of serous fluid were found in the peritoneal cavity, and the liver reached 4 cm. below the costal margin. The heart was greatly enlarged and weighed 675 grammes. The right auricle and ventricle were much dilated and formed the greater part of the organ. The mitral valve was reduced to a slit-like aperture by fusion of the cusps and fibrous thickening. The aorta throughout was thickened and scarred and showed numerous atheromatous plaques, atheromatous ulcers, and calcified areas. Below the cœliac axis the atheromatous process was especially marked. Just above the bifurcation a shelf of dense hard tissue with irregular edges projected into the lumen. On its upper side was a greyish-red thrombus which further occluded the already narrowed lumen. About 1 cm. above the bifurcation of the aorta was a pinkish-grey occluding thrombus firmly attached to the wall. This extended downwards into the common iliac arteries for a distance of 3 cm. in the left and 2 cm. in the right. On the right side the thrombus was evidently more recent than on the left; it was more pinkish and not so dense. On the left side the thrombus was completely organised, very dense, nearly white, and cut with much resistance. In fact, the vessel suggested a fibrous cord. The iliac arteries just below the thrombus were much sclerosed. There was also moderate general arterio-sclerosis. Microscopic examination of the aorta below the shelf mentioned showed great thickening of the adventitia and degeneration of the elastic fibres of the media. Around one-half of the vessel, partly in the media and partly in the intima, was an area composed of osseous tissue with large spaces containing red marrow in which all types of marrow cells were present. In the neighbourhood were large collections of osseous deposit. The bone showed a definite lamellar structure and numerous typical bone corpuscles. With high magnification a layer of cells resembling osteoclasts, and forming a membrane covering the osseous tissue, could be found. A number of scattered cases of heteroplastic bone formation can be found in medical literature. The following sites have been given: vessel walls, mucosa of the bladder, laparotomy scars, lung, pia and choroid plexus, dura, pleura, eye, stomach, liver, lymph nodes, heart valves, adrenals, and testes. More careful examination would probably show that the condition is commoner than is supposed. Kryloff estimates that in 15 or 16 per cent. of all cases of advanced arterio-sclerosis there is bone formation. In 1826 Andral described a case in which it was present in the aorta of a girl aged 8 years, and five or six cases in patients between the ages of 16 and 24 years. He also referred to a case of ossified temporal artery in an infant aged 15 months. Howse in 1877 found in an axillary artery a focus of bone. In 1866 Paul demonstrated at the Pathological Society of London a portion of a sclerotic tibial artery with a focus of osseous tissue in the intima. Considerable experimental work has been done on metaplastic bone formation. It has been produced in the kidney by ligature of the renal artery. Care must be taken in calling a process metaplasia, as the distinctions from various processes of growth are not so sharply defined as is generally supposed. Ziegler defines metaplasia as "that process by which a fully developed tissue is changed into another tissue without passing through an intermediate cellular stage." It is a well-known physiological process and occurs at all periods of life. The most common examples are the conversion of connective tissue cells into fat cells and of cartilage into bone. Such closely allied processes as heterotopia, in which there is a congenital or acquired snaring of cells of a tissue with subsequent growth out of place, must not be confounded with metaplasia.

SLEEPING SICKNESS IN THE ISLAND OF PRINCIPE.

WE drew attention recently[1] to the hopeful attitude adopted by Professor John L. Todd, of Montreal, regarding the possibility of ultimately preventing the occurrence of human trypanosomiasis in tropical Africa, notwithstanding the somewhat gloomy opinions expressed by some other experts upon the subject. Since then we have seen a report[2] on sleeping sickness in the island of Principe, written by Surgeon-Captain Bernardo F. Bruto Da Costa, chief of a commission appointed by the Portuguese Government in 1912 to investigate the prevalence of the disease in the colony. This report gives a sanguine view of the situation, and goes so far as to say that if the means indicated by the commission were provided by Government the malady could be eradicated within a year. It has, however, to be borne in mind that the problem is less difficult in Principe, an island some distance from the African mainland and with a population numbering not quite 5000, than it is in other parts of West Africa where re-importation of infection is easy and frequent. The chief industry of the island is the cultivation of the *cacao* plant, this being done mainly by imported labour. For many years sleeping sickness has been prevalent in Principe, which is about the size of the Isle of Wight, situated in the Gulf of Guinea, 135 miles from Fernando Po and nearly the same distance from the West African coast. It is stated that at one time the disease threatened the extinction of the entire population. Little, however, has been done until lately to check the spread of the infection, the planters and the natives having been equally apathetic. The special measures recommended by experts previously sent to deal with the malady were allowed, as Captain Da Costa says, to remain on paper "to the grave disgrace of agriculture and humanity." The late commission began its labours in August, 1912, and although at first they met with the same passive resistance as their predecessors, in time they convinced the planters, who are now eagerly coöperating with the staff of the commission. The report deals with ten months' work done by Captain Da Costa's "official brigade" in conjunction with the planters. The "official brigade" comprised 150 men, imported labourers, along with some convicts, who, however, were carefully trained to carry out their duties. The action taken included the draining of swamps and swampy land, the felling of timber in places where shade was afforded to the tsetse flies, the eradication of secondary growth of jungle-scrub, the clearing of the beds of streams from obstructions, the slaughtering of pigs and other animals running wild on which the glossinæ were found to feed, and the trapping of these flies by means of men wearing black cloaks or coverings on which had been smeared birdlime or some other sticky stuff. This plan for trapping tsetse flies was devised some years ago by a Principe planter named Maldonado, and we described it in THE LANCET of Feb. 12th, 1910. In addition to the above measures, medical inspection of the workpeople of the island was carried out in order to discover unrecognised cases, 125 such instances being brought to light. The blood of a number of domestic and other animals was examined to ascertain if trypanosomes were present; 52 of the animals were found infected, and they were at once slaughtered. During the ten months' period that the "official brigade" was at work, 235 wild pigs were killed, 251 "lagaias," and 272 dogs; besides these, 300 other dogs were destroyed in the small urban district of Sao Antonio which Captain Da Costa found in an extremely insanitary condition. Some attempt was made to protect domestic animals against trypanosome infection by administering injections of atoxyl, but this plan turned out to be inefficacious. The number of tsetse flies caught in the above-mentioned period by Maldonado's method was 110,691. Directions were given that anyone bitten by a glossina fly should at once receive a hypodermic injection of atoxyl. All persons proved to have trypanosomes in their blood were immediately isolated. After these measures had been in operation a few months there was a marked decrease in the number of cases of sleeping sickness and in the number of tsetse flies observed upon the plantations, amounting in some instances to entire disappearance. Captain Da Costa, as has been said, expresses the confident opinion that if the measures described above were fully carried out and the "official brigade" increased in number, sleeping sickness could be eradicated in Principe within a year. Principe, it may be added, is characterised by some authorities as "the garden of Africa," owing to its fertility and the richness of its vegetation. It is a pity that Captain Da Costa has not given us statistics of the incidence of sleeping sickness in the island in previous years for comparison. He, however, states that during the ten months' period ended May, 1913, 362 persons were under treatment for the disease.

[2] Sleeping Sickness in Principe. By Surgeon Captain Bernardo F. [illegible]

PERFORATION OF THE STOMACH IN TYPHOID FEVER.

ULCERATION of the stomach in typhoid fever is very rare. Perforation is still rarer; indeed, it is difficult to find a case on record which will bear examination. Hence the importance of the following case reported at a meeting of the Société Médicale des Hôpitaux of Paris on Nov. 14th, 1913, by M. A. Bergé and M. Barthélemy. A man, aged 21 years, was admitted into the Broussais Hospital on April 30th, 1913, suffering from fever and catarrhal pharyngitis. On the following days the temperature rose by steps from 100·4° to 102·2° F. On May 10th diarrhœa, rose spots, and slight albuminuria appeared. The spleen became slightly enlarged, and on the 20th the typhoid bacillus was cultivated from the blood. But the serum reaction was persistently negative. From the 15th the patient complained of pain in the left hypochondrium. The pain lasted for a fortnight, with variations in intensity, and then disappeared. There was no vomiting or other gastric symptom. The attack ran a usual course, except that the diarrhœa continued for a long time. The temperature progressively fell and became normal on June 3rd. The patient took nourishment well and gained strength, but did not put on flesh. He was discharged on June 30th. On July 3rd he was readmitted in a state of profound collapse, with cadaveric pallor of the face, cyanosis of the extremities, and subnormal temperature. On the 4th there was marked dyspnœa, a thready pulse of 104, and a rectal temperature of 96·8°. All over the chest bronchitic râles were heard. The abdomen was slightly distended, supple, and was not painful. The patient was almost unconscious, and passed abundantly yellow diarrhœic motions. He did not vomit, and died in a state of collapse. At the necropsy the body was found extremely wasted. The peritoneal cavity contained 200 grammes of sero-fibrinous liquid. The intestinal coils looked almost normal. On the ileum, about three or four centimetres from the cæcum, was a reddish zone with slight fibrinous exudate but no perforation. Further on the intestine was attached to the peritoneum lining the pelvis by a slight fibrinous cord. Inside the intestine at these two points were healed ulcers. Other healed ulcers were also found. The mesenteric glands were swollen, and one contained thick greenish-yellow pus. The spleen was very large and soft, and at its hilum was an abscess of the size of a mandarin orange. It was limited anteriorly by the posterior surface of the stomach, externally by the spleen, and posteriorly by peritoneal adhesions. On opening the abscess by removal of the spleen an infundibuliform depression was seen on the stomach, which led to a perforation. Viewed from inside the stomach the perforation was round and smaller than a 50-centime piece. Its borders were regular and appeared to be cicatrised. The right pleura contained about 100 grammes of hæmorrhagic fluid. The bases of the lungs were congested. It might be suggested that the gastric lesion was an ordinary round ulcer which had perforated during the course of typhoid fever. However, the appearance of the ulcer and the absence of hæmatemesis and other gastric symptoms were not favourable to this hypothesis. It might also be suggested that an extra-gastric abscess originating in a lymphatic gland or in the spleen had perforated into the stomach. Against this view was the integrity of the spleen and the absence of a probable cause of such an abscess. It appeared that a typhoid ulcer of the stomach had perforated and produced the abscess, and that the condition ran a latent course before producing the final collapse. Perforation of the stomach in typhoid fever is so rare that Professor Chauffard in his erudite Thèse de Paris does not mention it. Millard has reported a case of typhoid ulcer of the stomach involving all the coats except the peritoneal which was transparent at some points.[1] M. Bergé and M. Barthélemy could find recorded only one case of gastric perforation in typhoid fever. Mazetti[2] has reported the case of a man who was admitted into hospital on July 18th, 1907, suffering from typhoid fever which ran an ordinary course except for persistent pains in the left flank, which began on July 30th. Apyrexia and convalescence began on August 11th, but on Sept. 7th an attack of subacute peritonitis occurred and rapidly proved fatal. At the necropsy a rounded perforation of the size of a two-centime piece was found on the posterior surface of the stomach near the pylorus. Its borders were abrupt and not indurated. There were several other gastric ulcers which were more superficial.

THE SHORTAGE OF ANATOMICAL SUBJECTS.

Professors of anatomy and teachers of operative surgery have for years been complaining of the difficulty of obtaining "subjects" for dissection, and beyond all doubt the teaching both of anatomy and of operative surgery has long been hampered by a deficiency in the supply of bodies. Twenty years ago the supply was beginning to fall off sufficiently to be felt, and it has steadily diminished year by year ever since. Things have got to such a pass now that the Royal College of Surgeons of England has been moved to action, and has pressed the matter upon the attention of the Home Secretary, but so far no concrete proposals for solving the problem have been put forward. The attention of the lay press has, however, been gained, and reminiscences of Burke and Hare have naturally undergone resurrection. This way prejudice gathers; and politicians are not likely to go out of their way to bestir themselves in a matter which can scarcely bring them votes in any event and is liable to be used as a party catchword against them. The public, too, is little moved by reasoning, however sane and cogent it may be, directed to showing the advantages of anatomical knowledge in physicians and surgeons, or the disadvantages of a lack of it. The medical profession must expect no help from without, but must produce its own schemes for increasing educational facilities in this respect and must be prepared for strenuous opposition from sentimentalists even to the most reasonable and necessary suggestions. In these circumstances teachers of surgery and the examining corporations in that science might well consider a plan which was suggested a year or two ago, we believe in America, and is said to have worked well. The adoption of this expedient would set free every year, and leave available for the teaching of anatomy, a considerable number of bodies which at present are used up in operative surgery classes and examinations. Briefly, the idea is to perform representative abdominal operations upon the pig under full anæsthesia, with complete aseptic precautions, the animal being treated with every care and attention. As matters stand, the operations practised in classes of operative surgery are largely those which Listerism has long ago rendered rare or obsolete; while the common procedures of the modern operating theatre are perforce omitted altogether from the course. The American scheme would not only do something, though not perhaps enough, to remove the difficulties of the teachers of anatomy, but would in addition enhance the value of training in operative surgery, which at present is not so great as it should be. There would, no doubt, be determined opposition to the necessary modifications of the vivisection laws, but at least here is a constructive contribution towards the solution of a difficult problem. We see its disadvantages as clearly as its advantages.

INSANITY AND AMENORRHŒA.

Since the discussion of the connexion between amenorrhœa and insanity at a joint meeting of the Obstetrical Section of the Royal Society of Medicine and the Medico-Psychological Association more than a year ago, attention has been directed afresh to the question whether there is or is not a form of insanity so closely connected with amenorrhœa that re-establishment of the menstrual function cures the mental disorder. In the *Australian Medical Journal* of Nov. 15th, 1913, the recent literature of this subject is summarised by Dr. J. W. Dunbar Hooper, who reports a somewhat remarkable case in point from his own practice. The patient when he first saw her was 21 years old. She was anæmic and constipated, and had suffered from melancholia for three years, during which time she had menstruated twice only, very scantily and with great pain. After more than 12 months of treatment, which included curetting, she was placed in an institution, where she spent a year. She was then found to be suffering from religious mania with amenorrhœa, was occasionally vicious, and at such times refused food. It was decided to remove an ovary and to substitute for it a more normal organ taken from a sane person. A hysterectomy upon another patient provided the required material, which after removal was placed in Ringer's solution at blood heat. Four and a half hours later the abdomen of the insane woman was opened. Both ovaries were very small, hard, pale, and cirrhotic. The more abnormal of the two was removed, the broad ligament on that side split, and the new ovary, cut into three slices, was embedded in the nest thus provided. Recovery was uneventful, and 24 days after the operation a normal, painless, profuse menstruation took place. The mental condition improved rapidly, and in six months the patient was dismissed to her home. She was then menstruating regularly, had put on 6 lb. in weight, and was exceptionally bright and happy. She declared her intention of doing her utmost to repay her parents for the trouble and expense of her treatment; in a word, her insanity had entirely vanished. Dr. Hooper

HEALTH TEMPLES IN ANCIENT GREECE AND THE WORK CARRIED ON IN THEM.[1]

By Richard Caton, M.D. Edin., LL.D. Edin. & Liverp., F.R.C.P. Lond.

The subject on which I have the honour of speaking to you this afternoon is of such wide range that in the time allotted I can only deal with it in bare outline. While knowledge as to the health gods, the shrines of healing, and the practice of medicine generally in ancient Greece has grown rapidly during late years, still there is much that is vague and uncertain as regards origin and the detail of methods. Egypt seems to have preceded Greece in medical lore and also in the superstition which accompanied it. How far Greece learned from Egypt it is hard to say, but there can be little doubt that many Egyptian methods were transported into Greece. The reference in the fourth book of the Odyssey to the superiority of Egypt in medicine is one proof of this; the adoption by the Greeks of the strange custom of incubation, long practised in Egypt, is another. In the dim twilight of Greek history Apollo was in some vague and distant way a healer. But by degrees minor deities who specialised more definitely in medicine took his place; they mostly were deified men, and of some of them I wish now to speak to you.

The Health Temple of Amynos.

The first I refer to, viz., Amynos, has been for centuries utterly forgotten, and indeed there is no reference to him in Greek literature until a later date, and then, curiously enough, only in the writings of the Christian Father Eusebius. His ancient cult was only rediscovered a few years ago. Amynos was an Athenian god of healing. His name doubtless comes from the Greek word αμυνεῖν, to protect, guard, defend, help. He was the helper and protector of the sick. When Professor Dörpfeld excavated the region of Athens between the Areopagus and the Pnyx he laid bare a part of the city forgotten and grass-grown for many centuries, containing streets, houses, and shrines, and among them the Amyneion or precinct of Amynos. Here I show you a ground plan of the region portraying small houses, narrow streets, water-pipes, and sewers. The Amyneion is an irregular area bounded by a wall with foundation of hard blue limestone, having a temple or chapel at its eastern side. In this plan of the precinct you see an altar or base of an image in the centre of the temple, also a sacred well. Many inscriptions were found.

Here is an attempt at a restoration of precinct and grove and of the ancient temple. Its date is best judged by the pottery, Attic black figured, proto-Corinthian of 700 B.C., and lowest of all Greek geometrical pottery of 900 or 1000 B.C. were found. The temple at that date would have a stone foundation with walls of sun-dried brick covered with cement. The colonnade and pediment, if existing, must have been of wood, the columns formed of rough pine trunks. No stone drums of column nor any parts of a stone frieze have been found. Many inscriptions of later date were discovered. The cult of Asklepios came to Athens about 420 B.C. Inscriptions are mostly to Amynos and Asklepios, and sometimes to them and Dexion (Sophocle Fragments of marble snakes are found, and numbe of remains of sculptured figures and ex-votc Here are some examples. Asklepios seems to ha been quite secondary to Amynos in the shrine, a up to Roman times Amynos holds his pre-eminenc Was incubation practised here? We have no info mation. A second foundation has been found whi possibly was the wall of a shed for incubation. N is anything known about baths, drugs, or metho of treatment. But treatment seems to have bee greatly valued, if we may judge from the inscri tions and ex-votos.

The Health Temples of Amphiaraos.

Secondly, I wish to speak of the precinct Amphiaraos near Oropus in Attica. This was t chief sanctuary of the god, though others existe as at Rhamnus, Argos, and Sparta. In a pleasi glen, well clothed with pines, planes, and oleande through which a stream flows and in which ma nightingales lift their voices, the shrine was bui Amphiaraos, a son of Melampus or Apollo, was a p historic warrior and a hero, one of the Sev against Thebes and one of the Argonauts. Wh flying from his enemies the earth opened ne Oropus and swallowed up Amphiaraos and chariot. Why he should have become a gr healing god it is hard to say.

On the north-west of the stream on a flat strip ground stand the remains of the sanctuary. M to the west are the ruins of the Temple Amphiaraos, a building 95 feet long and 43 w having a broad columned portico at the east e six columns between antæ. The cella had th aisles, separated by rows of columns. At the sou west end was apparently a small porch 8 feet b A large square base stood near the centre of t cella, on which no doubt stood the great image Amphiaraos—part of a colossal arm found w doubtless part of the figure—it was rather near the eastern end than the west. Probably t temple was not hypæthral, for if so rain wou fall on the god; louvres more probably lighted t cella. In front of the temple stood a large alta 28 feet long and 14 broad, built of limestone. was dedicated to several gods. Three long curve steps are seen on the north of the altar, on which n doubt worshippers stood or sat. The sacred sprin rises a few feet south of the altar, and was used fo special purposes only (not for washing hands no for purification). Amphiaraos rose as a god fro this spring—hence its sanctity. North of th temple and altar stood a large number of pedesta bearing statues.

North-east of the temple is a large stoa 360 fee long and about 36 wide. It has an open Dori colonnade of 49 columns on the south-east side, the other three sides having solid walls. At each end is a chamber about 24 feet wide, and between them a long space of 310 feet (gratings in separation walls). A central line of 17 Ionic columns divided the stoa into two aisles. A marble bench ran along the back wall. The inner face of the wall was stuccoed and painted. Traces of painting still remain. This was the abaton, enkoimeterion or ward; the women occupied the western end, the men the eastern. Behind the colonnade, excavated from the hill side, is the theatre, with circular chorus space about 40 feet wide. The stage was about 40 feet by 20. North-east of the abaton o ward is a series of bath rooms, ten in number, dating from the third century B.C., but Roman alterations are evident. Two rooms have a hypocaust. Men and women had separate rooms.

---

[1] A paper, illustrated by 60 lantern slides, read before the Section of the History of Medicine of the Royal Society of Medicine, on Dec. 17th, 1913.

The inscriptions indicate that the sanctuary was ounded at the end of the fifth century B.C., and that it was closed during winter. The priest was obliged to be present not less than ten days in each month and never to be absent more than three days at a time. The nakaros or sacristan was to attend regularly to his own duties. Any patient misbehaving might be fined five drachmas. On admission each patient paid a fee of not less than nine obols. The priest, when present, must pray over the victims and put their flesh on the altar. The shoulder of every animal sacrificed, and in some cases both shoulders, were given to the priest, also the skin was ultimately his property. The patients might eat most of the flesh of the sacrificed animal, but no part of it might be taken beyond the precinct. The nakaros wrote down all the names and addresses of the sick. Before incubation each patient sacrificed a ram, and he used its skin as a bed, lying upon it in the abaton. Then incubation commenced, and he nightly awaited dreams and visions of the god.

Whether or not any drugs were given, no one knows. A special diet with occasional abstinence was enjoined—fasting from all food for one day and from wine for two. No beans were allowed. When recovery took place the convalescent dropped gold or silver coin into the sacred well (which offering presumably was subsequently abstracted by the priest). Models in gold or silver of the diseased organ or limb were suspended in the temple near the figure of the god. Many gold and silver vessels and ornaments were given. There was a festival of the god every fourth year. That is all that is known.

The shrine of Trophonios of Lebadea near Thebes had a lesser vogue for cure of the sick. The methods were somewhat the same: incubation and sleeping on the skin of a black ram.

Asklepios: the Temple at Epidaurus.

It is difficult to date the rise of the cult of Asklepios—probably it was later than that of Amynos—but it dates back to Homeric times. Tricca was probably its source, but Epidaurus the great centre where it chiefly flourished and whence it spread to all parts of Greece, Magna Graecia, and Rome. The site of the Hieron was six miles inland from the town of Epidaurus. At the time of its greatness an extensive precinct occupied the beautiful valley extending from the hill Titthion, where Asklepios was suckled by a goat, to Kynortion, on which stood the Temple of the Maleatean Apollo. Here is a rough bird's-eye view of the precinct as seen from the south—a splendid array of temples, stoæ, a great theatre, a stadium and grove. Here is the gateway with well for ceremonial purification, and the northern boundary wall. Here is the central temple of Asklepios, built in the fourth century B.C. The eastern façade presented a richly decorated and coloured scheme. The eastern pediment represents a combat of Greeks and Amazons, the western a conflict with Centaurs—Victory on the apex, and Nereids as acroteria; an elaborate ivory door. A side view of the temple shows the works of art adjacent to it, and behind it a part of the abaton. A sketch of the interior shows the splendid gold and ivory figure of the god with a golden serpent and a temple dog. Chryselephantine sculpture is very beautiful; the ivory, however, tended to crack, as was found at Athens and Olympia. But this great figure of Asklepios never required to be moistened with oil or water, as did the others, for the god of physic we may presume knew how to preserve his own integument. Only the floor of this temple and fragments of its decorations remain.

The abaton, or enkoimeterion, or hospital ward was employed probably half for men and half for women. On the south it has an open colonnade. So whatever other therapeutic agencies were employed there is no doubt that pure fresh air was enjoyed by the sick who occupied it. At the west end it was two storeys in height. Here incubation took place, the sick awaited the personal aid of the god or of the serpents, or they hoped for dreams or visions guiding them as to the best treatment for their several ailments.

Here is the Tholos or Thymele, an extraordinarily beautiful building of white marble coloured in parts. It was the most splendid circular building ever erected by the Greeks, dating from the third century B.C., built by Polykleitos the Younger. It was Doric externally, Corinthian within. Within were two celebrated paintings, Methe (drunkenness) and Eros, suggesting the relation of Dionysus and Aphrodite to the ailments which afflict mankind. There are various opinions about the function of the Tholos. Some think it was the sacred well. The foundations are curious, a dark labyrinthine basement, which I think cannot have been a water-tank, because, firstly, it was not cemented and would never have held water; secondly, there is no spring nor conduit leading to it; thirdly, the word Thymele means a sacrificing place; and fourthly, Pausanias speaks of the Tholos and the sacred well as entirely distinct. I have little doubt that it was the home or lair of the sacred serpents; in the vaults beneath they dwelt and bred in numbers, and from here they were sent to the numerous asklepieia all over the ancient world. The snakes would ascend to the floor of the tholos, where bloodless sacrifices were offered to them, and where the sick gave them the honey cakes, popana, and other sacrificial delicacies they were fond of.

[Dr. Caton then exhibited a lettered sketch of the Temple of Artemis Hekate.]

On the side of the hill Kynortion is seen the theatre, which was built in the fourth or fifth century B.C. by Polykleitos. Pausanias tells us it is the most interesting of the Greek theatres of his time. It certainly is one of the most beautiful of those existing to-day. The koilon or auditorium consisted of 55 rows of marble seats, capable of seating, it is said, 12,000 spectators. The chorus space is circular. The stage was 11 or 12 feet above the chorus space. The acoustics of this theatre are perfect; a loudish whisper on the stage is heard in every part of the auditorium. How many thousands of people have here listened to the plays of Æschylus, Sophocles, or Aristophanes!

Ceremonial Rites.

Vast numbers of the sick came here from all parts of the Greek world and beyond it. They lodged doubtless in the great hostel and in tents; those who were undergoing incubation of course slept in the abaton. At times—as, for example, at the festival of the Megale Asklepieia—thousands came who merely wanted a holiday, just as they came to the Isthmian or the Olympic Games. The patient on arrival underwent ceremonial purification, then paid his fee and arranged with one of the hieromnemones about his accommodation. He would walk in solemn procession to the temple with singing of sacred pæans, with music of lyre and double flute, and burning of incense. He would enter the Tholos and, if I am correct in my theory, offer bloodless sacrifices to the snakes, feeding them with honey, cakes, &c. He bathed in the sacred fountain, performed certain rites, and offered his sacrifices. Priests and physicians probably arranged his diet and treatment. At night he enters the abaton, bringing his bed clothing, and reposes on one of the couches. At nightfall the nakoros lights the lamps. The priest enters and recites the evening prayers to the god. Here is one that has come down to us in the writings of Ælius Aristides, a priest of Asklepios. "O ye Children of Apollo, who for many in past time have stilled the waves of sorrow and shown a light of safety for those who travel, be pleased to receive our prayer which ye inspire in sleep and vision. Order it rightly, we pray you, according to your loving kindness. Preserve from sickness, give the body such measure of health and strength as may enable it to obey the spirit within; that our days may be passed in vigour and in peace." Silence was then enjoined, the lights put out, and the priest commanded all to fall asleep and hope for guiding visions from the god. The serpents would probably visit the sick. Their visits were most welcome. These serpents were of course tame and harmless. The phrase in the inscriptions ἰασατο τῇ γλώσσα refers to their habit of licking an injured part.

The Records of Miraculous Cures.

The inscriptions speak of the god often appearing to the sick, of miraculous cures and of visions. Here follow examples. Hermodikos was paralysed. In his sleep the god told him to go out on to the hill side and bring in the largest stone he could find. He brought it in and it now lies before the abaton. The stone it is believed lies there to-day, but no man is strong enough to lift it. A man suffered from a malignant sore on the foot. While sleeping a serpent licked the foot with its tongue. The sore was at once healed. Hermon of Thosos was blind. His sight was restored by Asklepios, but Hermon did not send the fees he had promised on his return home, so the god again made him blind. He came back to the hieron with the fees and was again cured. A man had an abscess in the abdomen. In a dream the god ordered his servants to hold him while he (Asklepios) opened the abdomen, cleared out the abscess, and sewed up the wound. When the patient awoke a great pool of blood was on the floor of the abaton, and he was cured. A great number of such inscriptions were fixed on the wall of the abaton.

In later times superstition had a less share and science a greater one in the work of healing. We read of the priests using reasonable and useful methods of treatment: diet of a plain and simple kind, hot and cold baths, poultices, various medicaments such as hemlock juice, oxide of iron, hellebore, squills, lime-water, and drugs to allay pain, active gymnastic exercise, friction of the skin, and counter-irritation. Bleeding was practised, as shown in this vase-painting, and surgical methods were in use, for reliefs of surgical instruments exist.

A Cruel Superstition.

Doubtless many of the sick benefited greatly, but some incurable cases came for help, and here a difficulty arose. Neither birth nor death was permitted by the Greek religion to occur in the precinct of a god. If any sick man failed to improve and was seen by priests and attendants to be obviously dying, instead of being tenderly nursed and soothed, he was removed from his couch, conveyed to the nearest gate, expelled, and allowed to die on the hillside unhelped and untended. Asklepios had rejected him, and no minister of the god might defile himself by any dealings with death. Sometimes, also, a poor woman anticipating maternity (who was being treated for some ordinary ailment) was suddenly and mercilessly expelled at the moment when she needed help and comfort most. This cruel law prevailed at all times, but in the days of the Antonines a home for the dying and also a sort of maternity hospital was erected outside the precinct.

The Benefits Derived by the Patients.

Apart from this cruel superstition, the sick seem to have been treated with kindliness and humanity, and they in general were benefited. The whole atmosphere of the place was helpful. The beauty of the landscape, the supreme art displayed in the buildings, the sculpture and the paintings on every hand, the charm of the sacred grove, of the cultivated flowers, and of the music, the solemn services in the temples, the plays in the great theatre, the exercises of the palæstra and the stadium, were constant sources of interest. Numerous semicircular seats or exedrae were provided in which the invalid could rest, the more cultured occupying themselves in the study of books from the library. The study of the innumerable votive offerings and commemorative tablets, recording cures, must have excited a beneficial faith and hope. The priests were men of culture and refinement, anxious to help and comfort. Look at this portrait of Asklepios, portraying sympathy and sorrow for the suffering. I think that, notwithstanding the superstition that prevailed, we can read in this face sympathy with suffering and an earnest desire to help. For those especially who had been initiated at Eleusis, and for whom advanced age or incurable sickness gave little prospect of life, the calm, dignified forms of Demeter, Persephone, and Iakchos would suggest patience and the hope of a pure spiritual after-life free from all bodily infirmity, for the Greek and Roman heart, as Ruskin tells us, was full of the hope of immortality.

The pure air of the mountains by night and day, the plain simple diet, the rest and change, and the medical treatment, the beauty and charm of the place made Epidaurus intensely popular among the Greeks, and the Christian teachers in the early centuries of our era found it more difficult to displace Asklepios than any other of the gods of Greece or Rome from the beliefs of their converts. It is quite evident from the writings of Ælius Aristides, who himself was a priest of Asklepios, that many of the members of the medical profession in towns and cities discarded the supernatural side of the worship of the asklepieia; indeed, I doubt if Hippokrates himself had any faith in it. His writings show little evidence of such belief. Of course, in the towns there were physicians practising on a purely secular basis, some of them supported by a local rate named the ἰατρικὸν. Some of these physicians had been trained at the asklepieia, others had secular training as pupils with private practitioners. How far the public trusted in Amyno phiaraos, or Asklepios rather than in the skill the doctor it is difficult to say; probably the jority hold these beliefs strongly.

IE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD ON INFANT AND CHILD MORTALITY.

N urgently needed investigation, on a commen-rate scale, has been undertaken recently by the dical Department of the Local Government ard respecting the actual and comparative idence of mortality in early childhood in each ministrative area of England and Wales, with ecial reference to the causes responsible for the ulting loss or impairment of human life. This bject has hitherto been dealt with piecemeal, and erefore, from a national standpoint, inadequately, the reports of the local medical officers of health; t as the methods of calculation and tabulation ployed are frequently dissimilar, the results for mparative purposes are untrustworthy.

Infant Mortality in 1908.

Commenting on this matter in his first annual port as medical officer to the Board, Dr. Arthur wsholme emphasised the fact that in the year 08 one-fifth of the total deaths in this country re those of infants in their first year of life. He ferred to the unequal distribution of this mortality, which at that time varied from fewer than to more than 150 in each 1000 births, and further dicated broadly the measures locally necessary for e effectual safeguarding of infant life.

From the year 1905 onwards the Local Government Board has issued to medical officers of health rms of tables for use in their annual reports, owing the number and causes of all deaths curring in their districts in each of the first four eeks, and in each of the 11 subsequent months of e. Inasmuch as many of these forms have therto been imperfectly filled up, supplementary quiry has been necessary in order to complete the cal information required for the exhaustive vestigation of infant mortality throughout the untry.

Inauguration of National System of Reports on this Subject.

In the year 1910 the introductory volume of what ay rightly be styled a national system of reports infant and child mortality was issued by the oard's medical officer, the object being to secure a rd's-eye view of the incidence of mortality during rly childhood in each of the 54 administrative unties of England, as well as to determine in hich of these areas further administrative action as called for in order to control excessive ortality at that stage of life. The endeavour was ade, in the first place, to ascertain whether reduc on of mortality in infancy necessarily affects juriously the health of survivors at the later ges; secondly, to indicate the communities xperiencing continuously high infant mortality; nd lastly, to determine the relative importance of e factors responsible for abnormal waste of life in hildhood.

A second volume of these reports has recently een issued by Dr. Newsholme. This is essentially continuation of his introductory volume already eferred to. It gives similar but much fuller statistical information respecting 241 administrative areas (mostly towns) whose populations vary between 20,000 and 750,000. In the aggregate these areas contain nearly three-fifths of the total population of this country.

For the first time the medical officers of those urban sanitary districts, among whom the waste of life is notorious, will now be able to ascertain the exact relative position of their districts, not only as regards the mortality at ages 0–1 and 1–5 years, but also as regards the mortality from various causes at different stages of infant life. The report is divided thus: the first part enumerates the detailed facts concerning the incidence of infant and child mortality; the close inter-relation subsisting between defective sanitation, poverty, and intemperance on the one hand and excessive infant mortality on the other forms the subject of the second part; whilst the third part contains a preliminary account of existing efforts for child welfare in this country.

The chief object of this report is stated to be the formation of a framework of facts on which further inquiry may be made both by the Board's medical staff and by the local officers of health. The report is intended to bring into relief the experience of those districts that still suffer excessive infant mortality; to show the amount of presumably avoidable loss of life; to indicate the circumstances under which this loss occurs and the reforms necessary to secure a minimum loss of infant life. The exact causes of excessive infant mortality are obviously complex; nevertheless, comparison between towns of low and towns of high mortality leads irresistibly to the conclusion that very much of the excessive mortality in the less favoured towns can be remedied, if only the appropriate measures are adopted.

Urban and Rural Infantile Mortality.

It is familiar knowledge that the conditions prevailing in most urban communities are unfavourable to infant life. From the report of the Registrar-General for 1911 it may be gathered that the urban infant is almost as healthy at birth as is the rural. During the first month of life, when more than one-third of the total infant mortality occurs, the urban excess is only 8 per cent. During the first three months the urban is only 11·6 per cent. higher than the rural rate of death, while in the next three months it is 43 per cent., and in the second half of the first year it is 67 per cent. higher in the urban than in the rural districts. Speaking generally, the towns having respectively a high or a low rate of infant mortality have similarly a high or a low mortality in the next four years of life. In some towns the children suffer more severely at ages 1 to 5 than in their first year. The conclusion previously stated would therefore appear to be supported, that a high infant death-rate in a given locality generally implies a high death-rate in the next four years of life, while a similar association is found between low death-rates at both age periods. In a previous report this comparison was followed up to the age of 20 years, and from this it appears that, speaking generally, the communities suffering from excessive infant and child mortality continue to experience excessive mortality, though in a less degree, at the higher ages.

Reduction of Infant Mortality in Recent Years.

Prior to the year 1901 there is no indication of any substantial decline in English infant mortality. The steady improvement from 1901 onwards is one of the most striking features of recent statistical history. Some conception of the life-saving thus secured may be gathered from the following illustration. In the seven years 1906–12 the deaths of 736,682 infants occurred in England and Wales, equivalent to an average rate of 115 per 1000 births. Had the infant death-rate been 144 per 1000, as it had been in the seven years 1899–1905, there would have perished 922,454 infants in the years 1906–12. The improved conditions imply a saving of 185,772 lives during these seven years.

Defective Sanitation, Poverty, and Intemperance affecting Infant Mortality.

Among the domestic forms of insanitation overcrowding and lack of cleanliness are the most detrimental to child life, and these fall most heavily on the poor. This usually means for the bottle-fed child unsatisfactory arrangements for the storage of food and the consumption of contaminated or partially decomposed milk. Among the defects of sanitation for which the local authorities are responsible the most injurious to infants are unsatisfactory methods of scavenging, defective paving of streets and passages, and insufficiency of water-supply. Respecting the effect of poverty on infant mortality, Dr. Newsholme observes that when poverty involves malnutrition of either the expectant or the nursing mother it is only reasonable to assume that injury to the offspring will occur. Statistics are quoted from the Registrar-General's report for 1911 which show that infant mortality increases with declining social position. The rate does not exceed 77 per 1000 births among families of the upper and middle class, whilst it is equal to 148 per 1000 among textile operatives and 160 among miners. But that these excessive death-rates are not necessarily connected with poverty is proved by the fact that the rate among agricultural labourers is only 97 per 1000.

We cordially recommend the two volumes of the series already published, as practically indispensable to students of modern vital statistics. As such they will doubtless be regarded, and probably acquired for reference by those who are responsible for the guardianship of the public health; they may also be profitably studied by those who contemplate future enrolment in the public health department of our profession.

FOURTH ANNUAL MEETING OF CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA.

At the annual meeting of Clinical Congress, which was held in Chicago between Nov. 10th and 15th, 1913, the attendance numbered about 4000. As on previous occasions the holding of clinics was a special feature for which the wealth of material and the numerous hospitals and institutions of Chicago proved especially favourable.

The opening meeting took place on Monday evening, Nov. 10th, under the presidency of Dr. **George Emerson Brewer**, of New York. Dr. **E. W. Andrews**, chairman of the committee of arrangements, introduced Sir **Rickman Godlee**, President of the Royal College of Surgeons of England, who said that he had been impressed with the enormous amount of clinical material he had seen at all the hospitals visited, and had been much struck with the methodical manner in which instruction was carried on at these institutions.

After some congratulatory remarks by Dr. **Murray McLaren**, President of the Canadian Medical Association, and by Professor **Krönig** a Dr. **C. J. Gauss**, of Freiburg, Dr. **Brewer** gave

The Presidential Address: A Preliminary Rep on a Simple and Rapid Method of Pyloric Closure in Gastro-enterostomy.

Dr. Brewer referred to the defects, as point out by Tappliner, of all simple methods of pylo closure, and after reviewing the various metho suggested in the past, described his method. Tl consists in constriction of the pylorus by aluminium band, which is easily passed round t tube at this point and is quickly rolled with t fingers into an unyielding ring with sufficie compression to obliterate the lumen of the tul but not to compromise the vitality of the co pressed tissues. Experiments upon dogs, he sa had shown that this method of closure produced complete occlusion of the pylorus, as evidenced the fact that water would not pass the constrict point when the stomach was distended, and al that sections through the pylorus and aluminiu ring showed, on both gross and microscopic exan nation, not only that the pylorus was close but that the vitality of the tissues was n impaired. Another series of experiments show that the same method could be applied to t pyloric antrum, and, further, that the pylor which had been closed for some months, could ha its function restored by a second laparotomy a removal of the aluminium band. Although t method had not yet been used on the hum subject, Dr. Brewer held that the animal expe ments had been so conclusive that he believed it be the simplest and safest method yet proposed such cases.

Operation on the Gasserian Ganglion.

Dr. **Harvey Cushing**, of Boston, reported a ser of 156 cases with only two fatalities.

On Nov. 11th Dr. **John B. Deaver**, of Philadelph read a paper on

Gastric Hæmorrhage.

He said that operation might be indicated i gastric carcinoma when hæmorrhage chance to be an early symptom and there was stil hope of cure, or in advanced, or otherwise in operable, cancer when hæmorrhage was so profus and persistent as to shorten even the period of prognosis. In this case the measures to be adopted were excision, gastro-enterostomy, or jejunostomy, according to the pathological condition found a operation. But four most essential questions remained to be settled: 1. The recognition o suitable cases. 2. The time to operate. 3. The type of operation. 4. The proof of our position by mortality statistics.

Dr. **A. J. Oschner**, of Chicago, said that one must not look upon gastric hæmorrhage primarily as a surgical emergency. As a result of the surgical possibilities established during the past few decades a feeling had arisen that every serious condition must be attacked surgically. But this was justifiable only when the good judgment of the surgeon indicated that the patient was in such good condition that surgical treatment would offer th greatest possibility of cure. A careful and accura diagnosis, based upon a thorough knowledge of the history of such cases, was the foundation for th judgment.

Mr. **Herbert J. Paterson**, of London, read paper on

The Operation of Gastro-jejunostomy and the Principles that should Determine its Use.

He thought that there was little doubt that th ediate results of the posterior operation were :er than those of the anterior. Convalescence more smoothly and vomiting was less common. :eover, the anterior operation might necessitate ;hing out the stomach during the first few days. to remote results, he thought the advantage :ed with the anterior operation. Mr. Paterson oted the greater part of his paper to arguments wing that the operation of gastro-jejunostomy is hysiological one, notwithstanding Sir Berkeley ynihan's expressed belief that the "physiological lanation of gastro-jejunostomy is rot." The r practical lessons, he said, were: 1. That the e of gastro-jejunostomy employed is of less ortance than the manner in which it is per- med. 2. That if gastro-jejunostomy be a siological operation its use for the treatment of tric hæmorrhage is correct and explicable. That occlusion of the pylorus is an unnecessary aplicati [illegible] based on oneous [illegible] unostomy a physiological operation, then it is as efficient reatment for ulcers of the body of the stomach for ulcers near the pylorus; in other words, stro-jejunostomy is preferable to excision.

Dr. CARL BECK, of Chicago, said that Mr. erson's remarks in regard to the anterior and sterior operations, as well as the relative merits each, were important and suggestive. As to ether pyloric exclusion was practically useless, ther experimentation was needed.

On Nov. 12th Professor KRÖNIG read a paper on

The Radiotherapeutic Treatment of Benign and Malignant Tumours.

said that they had treated 254 cases of ncer with Roentgen rays and radium, 150 of em on purely therapeutic lines and without eration. Of these 150, 140 were treated with entgen rays and mesothorium; in 10 the entgen ray alone was used. Of 64 cases of rcinoma 43 cases had been treated for the pre- ntion of secondary growth almost exclusively th unfiltered Roentgen rays, while 21 cases were ated partly with filtered and partly with un- tered rays. The difference was striking. While out of the 43 cases died of carcinoma, they had en able to follow the subsequent history of 20 out the 21 cases and found that 60 per cent. of the currences occurred the first year after operation. ecurrent cancer had been treated with radioactive bstances. The 140 cases treated with Roentgen ys and mesothorium should be differentiated into o groups: 1. Those in which carcinoma had t spread beyond the primary focus into the ighbouring tissue, and in cancer of the cervix ere the carcinomatous growth had spread into e parametrium and glands, so that operation was t of the question. 2. Those carcinomas in which ditional metastases were already present. While had been found possible to produce remarkable trogressions and checking of the carcinomatous etastases by intense radiation of Roentgen rays d radium, in all cases the carcinoma had spread ter on. They could not say they had saved a ngle patient. In the second group the majority cases were at the present time impossible of re.

Dr. HOWARD A. KELLY, of Baltimore, said he had nployed radium in 188 cases of malignant growths. e had treated 40 cases of cancer of the lower part the uterus, where the disease was apt to spread pidly, and the cases were considered hopelessly lvanced and inoperable, and in three of these, after extensive operation, radium was used. In these three cases there had been no recurrence and health had been fully restored. He had also had four cases inoperable on account of the patients' general condition, where apparently a cure had resulted. Dr. Kelly thought that with an abundant supply of radium its use for superficial cancer would yield better results than surgery.

(To be continued.)

MEDICINE AND THE LAW.

Post-mortem Examinations and the Consent of Relatives.

A JUDGMENT delivered recently by Lord Anderson in the Court of Session, Scotland, is of interest to those called upon to make post-mortem examinations. In the case in question an action for damages (we use English phraseology rather than the less familiar Scottish legal terms) was brought by Mrs. Hughes, the widow of a deceased miner, against Dr. R. C. Robertson on the ground that he had made a post-mortem examination of her husband's body without authority, and that he had destroyed certain parts of the body instead of replacing them for burial with the rest of it. The action was successfully defended for Dr. Robertson by the Medical and Dental Defence Union of Scotland, Lord Anderson being of the opinion upon the evidence that the defendant had sufficient authority for what he did, and that he had in fact restored the heart to the body, although he had burnt portions of the intestines, a course justified by their decomposed condition. It is not necessary to recite the facts upon which this decision was based and which amply justified it, but it may be mentioned that there had been, or was alleged to have been, an accident, injuring the abdomen of the deceased, that after a day or two he had gone to the infirmary at Kilmarnock, that an exploratory examination had been made by the defendant who is one of the surgeons of that institution, that the patient's condition had proved to be very serious, and that two days later he died. To this it may be added that there was evidence that a suggestion was at some time made by the deceased both to Dr. Robertson and to Dr. A. Revie, the medical officer of the colliery, that the deceased had made an indiscreet meal of whelks and chip potatoes, and that the widow and dependents afterwards made a successful claim before the sheriff substitute under the Workmen's Compensation Act. It will readily be understood that in these circumstances the probability of a post-mortem examination being required by the relatives was taken into consideration, together with direct evidence as to some of them (but not the widow) having asked Dr. Robertson to make one. It is of more general interest, however, to note the points of law referred to by Lord Anderson, not because they have any element of novelty, but because his lordship's judgment shows that principles established in such matters are not likely to be departed from. With regard to this Lord Anderson said emphatically, "It is quite well settled by the cases of Pollock *v.* Workman, 2 Fraser, and Conway *v.* Dalziel, 3 Fraser, that an unauthorised post-mortem examination is a legal wrong." This, he explained, was on the principle that distress might be caused to relatives by the dissection of the body of one who in life was dear to them, and he referred to the damages in such a case as a solatium for injured feelings. As to the alleged abstraction and detention of parts of the body by those performing the examination Lord Anderson said: "This may, and perhaps does, *per se* found a claim for damages; but it is difficult for me to appreciate the attitude of mind which resents such an action and at the same time condones the dissection of the body." A point not of law, but illustrating the condition of fact, arising in such a case may here be noted. It was put forward that the relatives who asked for a post-mortem examination assented only to such an investigation as would not necessitate any dissection. Lord Anderson came to the obvious and reasonable conclusion that the persons who dealt with the matter, if they wanted evidence to establish the fact of an accident, required and intended to ask for such an examination as would be necessary for that purpose, which, of course, would involve opening the body. Among the defences formally raised was one to the effect that the deceased was being treated in a public charitable institution, that the defendant was acting partly, at any rate, in an official capacity as surgeon to the Kilmarnock Infirmary, and that as such he was obliged to give a certificate of the cause of death. Lord Anderson said as to this: "I do not think the court can too emphatically lay down, nor can medical men too distinctly and constantly keep in mind, that a medical practitioner in circumstances like the present has no right apart from authority to dissect a dead body." The question whether the authority for this purpose should be in writing was referred to. As to this the learned judge observed that it was not in his opinion essential. Authority could be proved by other evidence, but he called attention to the advantages of a written authority in such a matter, and intimated that medical men would be taking a useful hint if as a result of the case before him they insisted upon it. The deduction, in short, to be made from a case of an unusual kind arising out of circumstances that are of not common occurrence is that a medical man about to hold a post-mortem examination at the request, or at the supposed request, of a private individual should have authority in writing for doing so, stating distinctly the nature of the examination; and should take care that the person signing that authority is so qualified by relationship or other circumstances that no one will be able to come forward and object as having a better right to be consulted. On the majority of occasions, however, in England at any rate, when post-mortem examinations are held, they are made by the order of a coroner or under some other authority, which fully protects the practitioner or pathologist, and the post-mortem examination made on behalf of private individuals is of comparatively rare occurrence.

Back-to-Back Houses and the Local Government Board.

The Chesterfield rural district council recently had the satisfaction of being upheld in its views with regard to a number of insanitary dwelling-houses by an inspector of the Local Government Board, who held an inquiry upon an appeal by the landlord. The houses in question were situated in Eckington, being back-to-back houses, and the requirements of the council were conversion of privies into water-closets, paving of backyards, general repairs, and the making of each pair of front and back houses into one house. The owner of some of the houses complained of insisted with regard to the last requirement that it would suffice if he put in ventilators instead of effecting the conversion demanded. Another landlord expressed willingness to comply, but awaited the result of the appeal of the first mentioned before doing so. A closing order was made by the rural district council under the Housing and Town Planning Act, 1909, and an appeal to the Local Government Board followed as stated. The inspector, upon the evidence of Dr. H. Peck, medical officer of health to the council, and other witnesses, and after inspecting the premises, confirmed the closing order made by the rural district council. Incidentally he declined to accept the contention put forward that the alleged existence of 16,000 back-to-back houses in Sheffield and similar conditions prevalent elsewhere justified their retention at Eckington. Dr. Peck, who is entitled to congratulation on his success in the matter, was cross-examined upon this point, and defined the relative progress of sanitation in Eckington and Sheffield neatly by saying, "They get what they can; we get as much as we can." It was pointed out that insanitary houses attracted and collected tenants of an undesirable character. This the inspector ruled to be irrelevant to the purposes of his inquiry.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

City of Birmingham.—The city of Birmingham is to be heartily congratulated on possessing a medical officer of the calibre of Dr. George A. Auden. The 1912 report shows the development of a system of inspection and treatment of a fine type in which an attempt is made to correlate all the agencies which have to do with child welfare and to deal with all the problems of special groups of defective children which arise in school work. Birmingham has recently taken within its borders certain outlying districts, and the centralisation of work thus involved has set free premises used as subcentres for inspection and treatment work in addition to the central office. And it is proposed to make the assistant school medical officers, with their headquarters at these subcentres, largely autonomous, with due regard to the necessities of central administrative control. The institution of five dental clinics is recorded, the central and suboffices are equipped for refraction work, an ophthalmic surgeon has been appointed, and an arrangement made for the supply of spectacles at cheap rates. It is proposed to build a central school clinic, so freeing the offices for clerical work, and in connexion with operations for tonsils and adenoids beds are to be provided and patients kept in for 24 hours. When the scheme is fully in operation Birmingham will be equipped for the amelioration of all those defects in school children, for which there is inadequate provision elsewhere, with the exception of deformities needing massage and special exercises. The report states that with the progress of the work the school medical department "is assuming more and more the character of a Central Bureau of Child Welfare." This admirable state of affairs is no doubt made possible by the broadly statesmanlike interpretation of the duties of the school medical officer, which is taken by Dr. Auden and the Birmingham Education Committee. This is best indicated by mentioning some points showing the range of the work. In the report is the account of 11 "parents' evenings," at which parents were talked to by Dr. An[illegible] Anderson; a table (novel in school reports) of deaths of children of school age is given, and is valuable as showing the causes of death most fatal. Out of 5[illegible] deaths 27·8 per cent. were from infectious diseases, 12 per cent. from diseases of the heart and pericardium, and over 9 per cent. each from pneumonia, accidents, and tuberculosis (including phthisis but excluding meningitis), and disea-of brain and meninges account for 7·8 per cent. Diseases of the lungs (other than phthisis) caused death in 2·4 per cent. A note by Dr. Hill emphasises the necessity (in order to get defective children treated) of effecting "some change ...... whereby the difficulties of parents are reduced." 1998 children suffering from illness have been notified to the medical officer by medical practitioners, and it is becoming possible in consequence to estimate the incidence of the various forms of chronic disease amongst school children. S

and the quadrangle

is recommended.

investigation into ventilation arranged under six typical methods, including the plenum system. Children in the Remand Home and at an industrial school are examined by the medical officer, who gives, as the result of an examination into the mental capacity of 20 boys at the latter institution, a report showing six as definitely mentally defective, one epileptic, and one borderland case. Emphasis is laid on the need for medical examination before committal. Ninety-six children on an epileptic register are examined every six months, and of these 41 are definitely improving. In 62 per cent. of the cases in which age at onset was noticed this was before five years. The open-air school, the physically defective, and the blind and deaf classes are reported on, and there are some especially valuable pages dealing with mental deficiency, not least of which is the report of personal observations made by an infants' mistress. The report from Birmingham shows what can be made of medical inspection and treatment in the hands of those who see the problems involved in a big way. It is earnestly to be hoped that some of the less advanced educational authorities will follow Birmingham's excellent example.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns, with an aggregate population estimated at 17,852,766 persons at the middle of 1913, 5565 births and 5070 deaths were registered during the week ended Saturday, Dec. 27th, 1913. The annual rate of mortality in these towns, which had been 13·2, 14·5, and 14·6 per 1000 in the three preceding weeks, further rose to 14·8 per 1000 in the week under notice. During the 13 weeks of the December quarter the mean annual death-rate in these towns averaged 13·9, against 13·7 per 1000 in London during the same period. Among the

The deaths referred to scarlet fever, which had been 37, 23, and 38 in the three preceding weeks, were again 38 in the week under notice, and included 7 in Birmingham, 6 in London, and 3 each in Liverpool, Manchester, and Sheffield. The fatal cases of enteric fever, which had been 14, 26, and 20 in the three preceding weeks, were again 20 during the week, of which number 4 were recorded in London, 2 in Portsmouth, and 2 in Hull.

The number of scarlet fever patients in the Metropolitan Asylums and the London Fever Hospitals, which had been 4143, 4137, and 4048 at the end of the three preceding weeks, had further declined to 3946 on Dec. 27th; 326 new cases were admitted during the week, against 524, 552, and 458 in the three preceding weeks. These hospitals also contained on the date mentioned 1113 cases of diphtheria, 181 of whooping-cough, 60 of measles, and 55 of enteric fever, but not one of small-pox. The 1215 deaths from all causes in London were 63 fewer than the number in the previous week, and were equal to an annual death-rate of 14·0 per 1000. The deaths referred to diseases of the respiratory system, which had been 227, 291, and 307 in the three preceding weeks, declined to 280, and were 6 below the number recorded in

During the 14 weeks included in the December quarter of

Burnley, and 32·1 in Bath.

The 6375 deaths from all causes were 1305 in excess of the number in the previous week, and included 346 which were referred to the principal epidemic diseases, against 341 and 348 in the two preceding weeks. Of these 346 deaths, 80 resulted from infantile diarrhœal diseases, 76 from measles, 76 from whooping-cough, 64 from diphtheria, 34 from scarlet fever, and 16 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·0 per 1000, and was equal to the rate recorded in the two preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 94, 96, and 89 in the three preceding weeks, further declined to 80 last week, and included 26 in London, 6 in Sheffield, 4 in Manchester, 3 in Tynemouth, and 3 in Swansea. The deaths referred to measles, which had been 54, 62, and 80 in the three preceding weeks, slightly fell to 76 last week, and caused the highest annual death-rates of 1·6 in Rhondda, 1·9 in Middlesbrough, 2·0 in Barnsley, 2·1 in Warrington, and 4·8 in Burnley. The fatal cases of whooping-cough, which had been 57, 56, and 61 in the three preceding weeks, further rose to 76 last week; of this number 11 occurred in London, 9 in Birmingham, 8 in Manchester, 7 in Sheffield, 6 in Liverpool, and 4 in West Ham. The deaths attributed to diphtheria, which had been 70, 69, and 60 in the three preceding weeks, rose to 64 last week, and included 11 in London, 7 in Birmingham, 3 in Leeds, and 3 in Willesden. The deaths referred to scarlet fever, which had been 23, 38, and 38 in the three preceding weeks, were 34 last week, of which number 5 were

last week, and were 137 above the number recorded in the corresponding week of last year.

Of the 6375 deaths from all causes in the 96 towns, 257 were attributed to different forms of violence, and 660 were the subject of coroners' inquests. The causes of 66, or 1·0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Hull, Nottingham, and in 63 other smaller towns. Of the 66 uncertified causes of death, 14 were registered in Birmingham, 11 in Liverpool, 4 in West Hartlepool, and 3 each in London, St. Helens, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,259,600 persons at the middle of 1913, 1025 births and 777 deaths were registered during the week ended Saturday, Dec. 27th, 1913. The annual rate of mortality in these towns, which had been 15·6, 17·0, and 17·3 per 1000 in the three preceding weeks, further rose to 17·9 per 1000 in the week under notice. During the 13 weeks of the December quarter the mean annual death-rate in these Scotch towns averaged 15·6, against 13·9 per 1000 in the 96 large English towns during the same period. Among the several towns the death-rate for the week ranged from 13·0 in Kirkcaldy, 13·4 in Perth, and 14·9 in Hamilton, to 20·5 in Falkirk, 24·8 in Greenock, and 28·9 in Coatbridge.

The 777 deaths from all causes were 26 in excess of the number in the previous week, and included 78 which were referred to the principal epidemic diseases, against 86 and 79 in the two preceding weeks. Of these 78 deaths, 37 resulted from measles, 11 from scarlet fever, 11 from whooping-cough, 10 from diphtheria, and 9 from infantile diarrhœal diseases, but not one from enteric fever or from small-pox. These 78 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·8, against 1·0 per 1000 in the 96 large English towns. The deaths attributed to measles, which had been 40, 36, and 39 in the three preceding weeks, fell to 37 in the week under notice, of which number 14 occurred in Glasgow, 8 in Edinburgh, 7 in Greenock, and 4 in Leith. The deaths referred to scarlet fever, which had been 8, 12, and 11 in the three preceding weeks, were again 11 during the week, and included 4 in Glasgow and 4 in Edinburgh. The fatal cases of whooping-cough, which had been 5, 6, and 3 in the three preceding weeks, rose to 11 in the week under review, of which 5 occurred in Glasgow and 3 in Paisley. The deaths attributed to diphtheria, which had been 12, 17, and 12 in the three preceding weeks, declined to 10, and comprised 4 in Glasgow, 3 in Aberdeen, 2 in Edinburgh, and 1 in Ayr. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 14, 13, and 14 in the three preceding weeks, fell to 9, of which 3 were recorded in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 123, 157, and 139 in the three preceding weeks, rose to 167 in the week under notice; 31 deaths were attributed to different forms of violence, against 30 and 32 in the two preceding weeks.

In the 16 largest Scotch towns 1138 births and 881 deaths were registered during the week ended Saturday, Jan. 3rd. The annual rate of mortality in these towns, which had increased from 15·6 to 17·9 per 1000 in the four preceding weeks, further rose to 20·3 per 1000 in the week under notice. During the 14 weeks included in the December quarter of last year the mean annual death-rate in these Scotch towns averaged 15·9, or 1·7 per 1000 above the corresponding rate recorded in the 96 large English towns. Among the several towns the death-rate last week ranged from 7·3 in Falkirk, 10·4 in Perth, and 14·0 in Motherwell to 21·7 in Glasgow, 22·3 in Dundee, and 28·9 in Greenock.

The 881 deaths from all causes were 104 in excess of the number in the previous week, and included 85 which were referred to the principal epidemic diseases, against 79 and 78 in the two preceding weeks. Of these 85 deaths, 50 resulted from measles, 12 from diphtheria, 11 from infantile diarrhœal diseases, 7 from scarlet fever, and 5 from whooping-cough, but not one from enteric fever or from small-pox. These 85 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·0, against 1·0 per 1000 in the 96 large English towns. The deaths attributed to measles, which had been 36, 39, and 37 in the three preceding weeks, rose to 50 last week; of this number 24 occurred in Glasgow, 10 in Edinburgh, 7 in Greenock, 3 in Paisley, and 3 in Leith. The deaths referred to diphtheria, which had been 17, 12, and 10 in the three preceding weeks, slightly rose to 12 last week, and included 4 in Glasgow, 3 in Aberdeen, and 2 in Edinburgh. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 13, 14, and 9 in the three preceding weeks, rose to 11 last week, of which 4 were recorded in Aberdeen and 2 in Dundee. The deaths attributed to scarlet fever, which had been 12, 11, and 11 in the three preceding weeks, further declined to 7 last week, and included 3 in Glasgow and 2 in Motherwell. The deaths referred to whooping-cough, which had been 6, 3, and 11 in the three preceding weeks, fell to 5 last week, and comprised 2 in Glasgow, 2 in Greenock, and 1 in Coatbridge.

The deaths referred to diseases of the respiratory system, which had been 157, 139, and 167 in the three preceding weeks, further rose to 184 in the week under notice; 30 deaths were attributed to various forms of violence, against 32 and 31 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of 1913, 350 births and 366 deaths were registered during the week ended Saturday, Dec. 27th, 1913. The annual rate of mortality in these towns, which had been 16·0, 17·7, and 18·9 per 1000 in the three preceding weeks, declined to 15·9 per 1000 in the week under notice. During the 13 weeks of the December quarter the mean annual death-rate in these towns averaged 17·2 per 1000; in the 96 large English towns the corresponding rate did not exceed 13·9, while in the 16 Scotch towns it was equal to 15·6 per 1000. The annual death-rate for the week was equal to 17·1 in Dublin (against 14·0 in London and 17·3 in Glasgow), 19·8 in Belfast, 10·9 in Cork, 11·4 in Londonderry, 13·5 in Limerick, and 11·4 in Waterford, while in the 21 smaller towns the mean death-rate did not exceed 9·2 per 1000.

The 366 deaths from all causes were 69 fewer than the number in the previous week, and included 31 which were referred to the principal epidemic [illegible] of the three preceding weeks. Of [illegible] from whooping-cough, 7 from scar [illegible] diarrhœal diseases, 3 from measles, 2 from enteric fever, and 2 from diphtheria, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·3 per 1000; in the 96 large English towns the corresponding rate did not exceed 1·0, while in the 16 Scotch towns it reached 1·8 per 1000. The deaths attributed to whooping-cough, which had been 4, 6, and 6 in the three preceding weeks, rose to 10, of which 7 occurred in Belfast. The deaths referred to scarlet fever, which had been 13, 8, and 8 in the three preceding weeks, were 7, and comprised 6 in Belfast and 1 in Newry. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 13, 6, and 11 in the three preceding weeks, declined to 7, of which 5 were recorded in Dublin. The 3 deaths attributed to measles were equal to the average in the earlier weeks of the quarter, and occurred in Dublin, Belfast, and Armagh respectively. The 2 fatal cases of diphtheria were recorded in Dublin, and those of enteric fever in Limerick and Galway respectively.

The deaths referred to diseases of the respiratory system, which had been 73, 92, and 80 in the three preceding weeks, rose to 89 in the week under notice. Of the 366 deaths from all causes, 92, or 25 per cent., occurred in public institutions, and 5 resulted from various forms of violence. The causes of 11, or 3·0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death did not exceed 1·0 per cent.

In the 27 town districts of Ireland 682 births and 593 deaths were registered during the week ended Saturday, Jan. 3rd. The annual rate of mortality in these towns, which had been 17·7, 18·9, and 15·9 per 1000 in the three preceding weeks, rose to 25·7 per 1000 in the week under notice. During the 14 weeks included in the December quarter of last year the mean annual death-rate in these towns averaged 17·8 per 1000; in the 96 large English towns the corresponding rate did not exceed 14·2, while in the 16 Scotch towns it was equal to 15·9 per 1000. The annual death-rate last week was equal to 30·4 in Dublin (against 18·6 in London and 21·7 in Glasgow), 25·4 in Belfast, 28·6 in Cork, 21·6 in Londonderry, 12·2 in Limerick, and 17·1 in Waterford, while in the 21 smaller towns the mean death-rate was equal to 20·5 per 1000.

The 593 deaths from all causes were 227 in excess of the number in the previous week, and included 32 which were referred to the principal epidemic diseases, against 36 and 31 in the two preceding weeks. Of these 32 deaths, 7 resulted from whooping-cough, 7 from measles, 7 from diphtheria, 6 from infantile diarrhœal diseases, 3 from scarlet fever, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·4 per 1000; in the 96 large English towns the corresponding rate did not exceed 1·0, while in the 16 Scotch towns it reached 2·0 per 1000. The deaths attributed to whooping-cough, which had been 6, 6, and 10 in the three preceding weeks, declined to 7 last week, and comprised 6 in Belfast and 1 in Newtownards. The 7 deaths referred to measles, of which 5 occurred in Armagh and 2 in Dublin, were 4 above the average in the earlier weeks of last quarter. The fatal cases of diphtheria, which had been 8, 8, and 2 in the three preceding weeks, rose to 7 last week, and comprised 4 in Dublin, 2 in Belfast, and 1 in Londonderry.

he deaths of infants (under 2 years) attributed to diarrhœa id enteritis, which had been 6, 11, and 7 in the three preceding weeks, were 6 last week, of which 3 were registered in ublin. The deaths referred to scarlet fever, which had eclined from 13 to 7 in the four preceding weeks, further ll to 3 last week, and were all recorded in Belfast. The fatal cases of enteric fever, which were equal to the weekly erage during last quarter, were recorded in Dublin and elfast respectively.

The deaths referred to diseas [illegible] hich had been 92, 80, and 89 [illegible] rther rose to 162 in the we[illegible] eaths from all causes, 173, or 29 per cent., occurred in ublic institutions, and 17 resulted from various forms of iolence. The causes of 26, or 4 4 per cent, of the total eaths were not certified either by a registered medical ractitioner or by a coroner after inquest; in the 96 large nglish towns the proportion of uncertified causes of death id not exceed 1 0 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Surgeons: *A. Simpson to the Isgard, temporary*; D. P. H. earson to the *Antrim*; D. G. Arthur to the *Halcyon*, [illegible] in to the *Doris*, and for [illegible] o the *Robin*, additional, [illegible] to the *Clio*, additional, [illegible] ayers to the *Britomart*, dditional, and on recommissioning; A. E. Malone to the *histle*, additional, and on recommissioning; G. F. B. Page the *Widgeon*, additional, and on recommissioning; A. J. *ozer to the Woodlark, additional, and on recommissioning*; [illegible] ecommissioning; and G. A. Bradshaw to the *Doris*, for edical charge on voyage home.

Fleet-Surgeon Edmund Corcoran has been placed on the etired List, with permission to assume the rank of Deputy urgeon General.

ARMY MEDICAL SERVICE

Surgeon General Owen E. P. Lloyd, V.C, C B., is placed n retired pay (dated Jan 1st, 1914)

Colonel Walter G. A. Bedford, C M.G, to be Surgeon-eneral, vice O. E. P. Lloyd, V C., C B. (dated Jan 1st, 1914)

Lieutenant Colonel Cecil Birt, from the Royal Army ledical Corps, to be Colonel, vice W. G. A Bedford, C.M G. lated Jan. 1st, 1914).

Colonel Thomas J. R. Lucas, C B., on completion of four ears' service in his rank, retires on retired pay (dated an. 2nd, 1914)

Brevet Colonel Robert S F. Henderson, K H P, from the loyal Army Medical Corps, to be Colonel, vice T. J. R Lucas, B. [illegible]

Ma [illegible] o be a epu [illegible] epart nent [illegible] War)ffice [illegible]

ROYAL ARMY MEDICAL CORPS.

[illegible] s on [illegible] to be [illegible] vice [illegible] 1914) [illegible] lated [illegible] an 3rd, 1914). [illegible] Southern Army in ndia.

Colonel R Kirkpatrick, C M.G, has been appoint[illegible] ssistant Director of Medical Services to the Sialkot a[illegible] bbottabad Brigades

[illegible]

[illegible] Karachi for Sout[illegible] troops. Lieutenant Colonel T. Du B. Whaite has been placed under orders to embark for a tour of duty in India, and on arrival will be appointed to hold charge of the Military Hospital at Lahore Cantonment, vice Lieutenant Colonel J. Fallon.

[illegible] as [illegible] Le [illegible] appointed to the Irish Command for duty in the Cork District. Major H W H O'Reilly has relinquished medical charge of effective troops at Colchester and embarked for a tour of service in India Major P. J. Probyn, D S O., has been transferred from the Military Hospital at Sheffield to Leeds. Major W. C. [illegible] of the Military Hos[illegible] Major E. W. Slayto[illegible] ment, tour expired. Major C. B Martin has been selected for appointment as Surgeon to the Royal Military Hospital [illegible]

[illegible] Major F. W. Begbie has been selected for advancement to [illegible] T. N. Thompson, D.S.O., [illegible] arrived home for duty [illegible] St C. Thom has been appointed to the Scottish Command for a tour of duty. Major J. H. W. Houghton has been selected for appointment as Specialist in Advanced Operative Surgery to the Military Hospital at Meerut Cantonment.

Captain D. Ahern has been placed under orders to join the Irish Command on Jan 17th and on arrival will be appointed to the Dublin District for duty. Captain H. V. Bagshawe has been transferred from the Military Hospital at Alexandria to Cairo Captain P. Power has been appointed to the [illegible] joined at Bradford Captain E. B. Booth has been placed under orders for transfer from the Military Hospital at Dundalk and embark for a tour of service in the Sierra Leone Protectorate Captain H. St. M. Carter has been selected for appointment as Specialist in Operative Surgery to the Cambridge Military Hospital at Aldershot. Captain D G Carmichael has been transferred from Khanspur, Murree Hills District, to the Military Hospital at Sialkot Cantonment. Captain M. C. Wetherell has taken up duty at the Military Hospital, Fethard, on transfer from Kildare. Captain C. P. O'Brien-Butler has arrived home for duty from India, by exchange. Captain A M. Benett has been appointed to the Scottish Command. Captain W Benson has been selected for appointment as Company Officer at the Depôt, Royal [illegible] the Ninth (Secunderabad) Division Captain R. G. S Gregg, specialist in operative surgery at the Military Hospital, Quetta Cantonment, has been placed under orders to relieve Major H. K Palmer at Aden, tour expired Captain H. T. [illegible] transferred from the Military Hospital at Preston to [illegible] has been selected for [illegible] l Science and Radio-[illegible]

INDIAN MEDICAL SERVICE.

[illegible] A. M. Crofts, C.I.E., has taken up duty [illegible] the Second (Rawal [illegible] India The Honour-[illegible], C.S.I., has been [illegible] ee months. [illegible] d has been selected [illegible] Director of Medical

Services to the Sirhind and Jullundur Brigades, vice Lieutenant-Colonel R. B. Roe. The services of Lieutenant-Colonel F. Jennings, superintendent of the Central Prison at Agra, on return from leave of absence, have been replaced at the disposal of the Home Department of the Government of India. Lieutenant-Colonel P. B. Haig has arrived home on leave of absence from India. The services of Lieutenant-Colonel H. W. Pilgrim have been replaced at the disposal of H.E. the Commander-in-Chief in India by the Home Department.

Rennie has taken up duty as Health Officer and Civil Surgeon of the notified area at Delhi during the absence on leave of Lieutenant-Colonel W. H. Ogilvie. Captain G. Holroyd has taken up duty as Superintendent of the Central Jail at Dacca, in succession to Captain F. H. Salisbury. Captain H. P. Cook has been appointed on plague prevention duty to the Fyzabad district. Captain J. A. Cruickshank has been appointed to the Bacteriological Department. The services of Captain S. J. Bhathena have been replaced at the disposal of H.E. the Commander-in-Chief in India by the Home Department. Captain J. Anderson has been appointed Civil Surgeon at Miranshah. Captain T. F. Owens, chemical examiner and bacteriologist to the Government of Burma, has been granted privilege leave of absence.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Cadet Staff-Sergeant Owen Hairsine, from the University of London Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated Nov. 29th, 1913).

TERRITORIAL FORCE.

Royal Army Medical Corps.

Major George St. Clair Thom, Royal Army Medical Corps, to be Deputy Assistant Director of Medical Services of a Territorial Division (dated Dec. 13th, 1913).

3rd Southern General Hospital, Royal Army Medical Corps: Captain William E. Robinson ceases to hold a commission in the Territorial Force (dated Jan. 1st, 1914).

2nd East Lancashire Field Ambulance, Royal Army Medical Corps: Supernumerary Captain George Ashton ceases to serve with the No. 18 Field Ambulance, Royal Army Medical Corps, Special Reserve, and is restored to the establishment (dated Jan. 7th, 1914).

3rd North Midland Field Ambulance, Royal Army Medical Corps: William Boyd to be Lieutenant (to be supernumerary) (dated Nov. 27th, 1913).

3rd London General Hospital, Royal Army Medical Corps: Captain Frederick R. Miller to be Major (dated Jan. 7th, 1914).

Highland Clearing Hospital, Royal Army Medical Corps: Alexander Gibbon to be Quartermaster, with the honorary rank of Lieutenant (dated Jan. 7th, 1914).

West Lancashire Clearing Hospital, Royal Army Medical Corps: Lieutenant-Colonel William Baron Cockill, from the 3rd West Lancashire Field Ambulance, Royal Army Medical Corps, to be Lieutenant-Colonel (dated Dec. 1st, 1913).

South Midland Clearing Hospital, Royal Army Medical Corps: Major Seymour Gilbert Barling, from the 1st Southern General Hospital, Royal Army Medical Corps, to be Lieutenant-Colonel (dated Jan. 7th, 1914).

Sanitary Service: Major Harold M. Richards resigns his commission (dated Jan. 7th, 1914).

Attached to Units other than Medical Units.—To be Captains: Lieutenant Andrew G. T. Hanks (dated Oct. 6th, 1913); and Lieutenant William C. F. Harland (dated Oct. 6th, 1913).

Captain George McKellar resigns his commission (dated Jan. 7th, 1914).

For Attachment to Units other than Medical Units.—To be Lieutenants: John Earnsclеuch Brydon (dated Jan. 3rd, 1914); George Paul Anning (dated Nov. 22nd, 1913); and William Douglas Frew (dated Dec. 1st, 1913).

Supernumerary for service with the Officers Training Corps.—The following Lieutenants serving with the Royal College of Surgeons in Ireland Contingent, Senior Division, Officers Training Corps, resign their commissions (dated Jan. 7th, 1914):—Thomas Thomson and Henry Stokes.

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Captain Charles Stuart Brebner, from the 1st London (City of London) Field Ambulance, Royal Army Medical Corps, to be Captain (dated Jan. 1st, 1914).

Surgeon-General William B. Bannerman, C.S.I., Indian Medical Service, has been appointed an Honorary Physician to the King in the place of Surgeon-Colonel J. Richardson, deceased.

ROYAL MEDICAL BENEVOLENT FUND.—At the December meeting of the committee 32 cases were considered and grants amounting to £284 made to 25 of the applicants. Appended is an abstract of the cases relieved:—

Widow, aged 58, of L.R.C.P. Edin. Husband died 18 years ago after a long illness, during which he was supported by the applicant. Is at present acting as nurse to a helpless invalid, but is obliged to give up because not strong enough for the duties. Voted £10.—Widow, aged 35, of M.D. No income; incapacitated by phthisis and requires help in order to go to a sanatorium; three children aged 12 to 5. Relieved twice, £10. Voted £10.—Widow, aged 46, of M.D. No income, and suffers from a spinal complaint by which she is quite incapacitated; two children, aged 6 and 5. Is endeavouring to obtain admission to a hospital for incurables. Relieved once, £5. Voted £18.—Daughter, aged 62, of late M.B. Lond. Only income £14 10s. a year, and has been disposing of her furniture to meet unavoidable expenses. Voted £12.—Daughter, aged 49, of late L.R.C.P., M.R.C.S. Is much run down after nursing her mother (recently deceased) through a long illness and is ordered a short rest before trying to find a post as companion. Voted £5.—Daughter, aged 63, of late M.R.C.S. Used to have a small school in a good London suburb, but was obliged to give it up owing to ill health and is now totally incapacitated. No income. Voted £12.—Daughter, aged 62, of late M.R.C.S. Has a small annuity, but finds when she has paid for a room and some attendance, which is necessary because she is nearly blind, there is not sufficient for other unavoidable expenses. Voted £5.—Widow, aged 62, of L.F.P.S. Glasg. No income and no relations or friends able to assist. Voted £12.—Daughter, aged 46, of late M.R.C.S. Has been an invalid for several [illegible] discharge of her duties as a nurse, [illegible] Has a pension from the British [illegible] be elected to one from another institution, but requires help for maintenance and necessary attention meanwhile. Voted £12.—Daughter, aged 56, of late L.R.C.P. Has a pension from a charitable society, but finds it insufficient for the bare necessities of life and is unable to supplement it by suitable work. Relieved six times, £29. Voted £12.—Daughter, aged 58, of late M.D. Edin. Used to support herself as a governess, but for some years past has been unable to obtain a permanent post in that capacity, and at present is dependent on precarious earnings from needlework. Relieved four times, £27. Voted £12.—Widow, aged 59, of L.R.C.P. & S. Edin. After husband's death endeavoured to establish a small boarding house, but was compelled to give up owing to failing health and is now practically incapacitated. No income, and dependent on a daughter who is a lady help. Relieved once, £10. Voted £10.—Widow, aged 85, of M.R.C.S. Only income an annuity of £10 and the Old Age Pension. Children unable to help. Relieved three times, £18. Voted £10.—Daughter, aged 66, of late M.D. Edin. Used to be a governess, but is now unable to earn for herself because obliged to attend to two invalid sisters. Only income £10 a year given by an old friend. Relieved eight times, £96. Voted £12.—Widow, aged 67, of L.R.C.P. Edin. Supplements an annuity of £20 from a charitable society by addressing envelopes, &c. Relieved 16 times, £151. Voted £10.—Daughter, aged 51, of late M.D. Edin. No income and has been a chronic invalid for some years. Voted £10.—Widow, aged 54, of L.S.A. Quite unprovided for at husband's death several years ago and supports herself by letting rooms and by needlework. Two daughters, both teachers, but barely self-supporting. Relieved eight times, £88. Voted £12.—Daughter, aged 59, of late M.D. Lond. Used to give music lessons, but is no longer able to obtain pupils and is dependent on a sister whose income is very small. Eyesight failing and suffers from chronic rheumatism. Relieved 30 times, £230. Voted £12.—Widow, aged 52, of M.R.C.S. Since husband's death has been endeavouring to establish a boarding-house in the town where he practised, and now finds that with the help from this fund she can just meet her expenses. Voted £12.—Daughter, aged 62, of late M.R.C.S. Endeavours to support herself by letting lodgings and keeping fowls; health very feeble. Relieved once, £12. Voted £12.—Widow, aged 68, of L.R.C.P. Edin. Has a small house which is let at a rent of £24, but the lease expires in a few years' time and repairs have to be frequently done. Relieved 14 times, £[illegible]. Voted £12.—Widow, aged 57, of L.R.C.P. Irel. No income; health indifferent; is at present a caretaker, but receives no salary. Relieved six times, £72. Voted £12.—Daughter, aged 55, of late M.R.C.S. No income and unfitted to earn her living. Relieved six times, £[illegible]. Voted £18.—Widow, aged 40, of M.R.C.S. Quite unprovided for at husband's death, and endeavours to support herself and two delicate children by selling old clothes on commission and by doing needlework. Relieved once, £10. Voted £10.—Daughter, aged 30, of late M.R.C.S. Was obliged to give up a post as typist some months ago owing to a complete breakdown in health, but hopes shortly to be well enough to start again. Relieved six times, £34. Voted £12.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos-street, Cavendish-square, London, W.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 62.)

XXIII.—INSURANCE IN HUNGARY.—THE GREAT STRIKE AT COLOGNE.

FROM Leipsic I proceeded to Frankfurt-am-Main d to Cologne, passing *viâ* Karlsbad, where I made me inquiries on my way as to the working of the surance law in Austria. All forms of organisa- on are difficult in Austria because of the great riety of nationalities that go to make up the mpire. These nationalities have different languages, ifferent religions, and different political aspira- ons, yet the Austrian insurance law is common to e entire Empire, so that the medical profession in is country can take hope as to the possibility of nion in dealing with the questions involved. The ungarian insurance law does not resemble the erman law as closely as does the Act of the erman-speaking provinces of Austria. In Germany mpensation for accidents is provided by employers ssociated according to their trades. In Austria his is done by the provincial administrations nd institutions. But so far as medical attend- nce and sick allowances are concerned, the ystem is the same in Germany, Austria, and ungary. In Germany, however, invalidity and ccidents are dealt with separately. In Hungary here is no provision for invalidity, but a joint dministration for providing against sickness and ccidents. The doctors complain that they are *ependent on the societies which administer the* nsurance law. These societies are not unlike our nglish Friendly Societies, only the Government orces the workmen to belong to them. The *anaging committees consist half of workmen and* alf of employers.

What Hungarian Insurance Doctors Earn.

Medical men can prescribe anything that is within the official Pharmacopœia, and this regardless f cost. It is not surprising, therefore, that the ocieties complain of the doctors' extravagance. hey even go so far as to accuse some *practitioners* f running up the drug bill so as to get a commission from the dispensing chemist. Doubtless this is one of the exaggerations that will arise in consequence of resentment. In Hungary the medical men are paid annually for each insured person from 5 to 7 kronen (4*s.* 4*d.* to 6*s.*). As this sum covers the families also, it will be seen that the pay is altogether insufficient. It has been calculated that this rate of payment works out at 6*d.* to 8*d.* per item, while in the very bad districts it falls to only 4*d.* per visit or consultation. The remuneration is so small that if on one or two rare occasions some less scrupulous practitioners have resorted to an unprofessional means of increasing their income, the fact, however deplorable, may be not altogether surprising.

In Hungary the doctors are supposed to receive 25 per cent. of all the contributions paid to the insurance funds, but it does not seem as if they had many insured persons entrusted to their care. Thus at Budapest, which is the most important centre, there is one great society, consisting of about 300,000 insured members. As, however, this society employs 560 medical men it can only allocate an average of some 540 insured persons to each of its medical officers. That is not much if only the income which such patients bring in is considered; but, as it includes the families as well, even making allowance for a certain number of bachelors, it must mean on an average a population of about 2000 for which each medical officer is held responsible. Even at the highest rate of payment, a capitation fee of 6*s.* for 540 insured persons equals £162 a year for attending the insured and their families, or about 2000 persons. The pay is thus reduced to a fraction above 1*s.* 7*d.* per head per annum. Miserable as this seems, I was assured it had only been obtained after many medical strikes, and is a considerable improvement on what used to obtain not many years ago. As an explanation it must be borne in mind that wages in Hungary are very low, and the subscriptions paid into the sick or insurance funds are correspondingly small.

A Five Years' Strike at Cologne.

When I reached Cologne I found, in a modified and mitigated form, the strike of 1909 was still continuing in 1913. But the medical men were in the main defeated, though they continue the struggle. The societies had formed themselves into a large trust, and in 1909 were able to engage the services of 60 medical men to replace the doctors who refused their coöperation. This is nearly double as large as the outside assistance which could be obtained during the strike of 1904, and therefore the Government had not the same cause to interfere by insisting that there should be enough doctors to attend on the insured. Nor were the 60 all imported; 14 of them were Cologne practitioners who had changed their views. Yet the opposition to medical views was not engineered without a struggle. The Cologne *Cassa* had to hunt all over Germany and, strange to say, it was at Leipsic that the greatest number of medical men willing to act against the interests of their profession was found. Large sums had to be offered to induce medical men thus to incur the opprobrium of their profession. In some cases as much as £500 a year, which is considered a large sum in Germany, and a contract for 10 years were offered. Then, to make their offers more tempting, the *Cassa* was willing to allow its medical officers to treat private patients and even promised to endeavour to secure such patients. A few societies have remained faithful to their old doctors and would not employ the imported strike-breakers, who are ignored by their professional brethren. There is a statute of the Leipziger Verband which forbids its members to consult with, or even to salute, a strike-breaker. Nor is any sort of acquaintance or association with the wives and children of strike-breakers allowed. The strike-breakers are practically boycotted; but they are, comparatively speaking, well paid. None of them are, as a rule, sent for to attend the visitors who frequent the hotels, and they have little or no connexion among the richer families. There are now about 82 doctors in the employ of the Cologne Insurance *Cassa*. I had an opportunity of speaking with one of the Government income-tax assessors, and ascertained that one of these imported doctors earned 9200 marks last year, or not quite £500; also it was shown that the profession has lost a great deal through the strike, perhaps as much as 1,000,000 marks (£50,000).

Raising the Wage Limit in Germany.

In spite of this great sacrifice the profession still believes a sort of victory will crown their strike, though it is now in its fifth year. They at least have succeeded in making it impossible for a medical man desirous to rank high in his profession to serve the *Cassa*. Formerly, when the doctors were paid according to the number of insured persons on their list, there was some abuse. This was notably the case in regard to the railway servants, the lists being too long. To-day the imported doctors are paid a fixed annual salary however many patients they may have to see. To make them diligent a system of bonuses has been instituted, and thus they obtain payments over and above their incomes for what is considered extra work, *pro rata* of that extra work. Perhaps the new law, though unfavourable to the interests of the medical profession in general, may be of help in respect to the Cologne dispute.[1] It was to have come into operation last year, but the complications were so great that its application was postponed to 1914.

There are so many societies and each *Cassa* is so differently organised that it is no easy matter to apply the new law. In Cologne alone there are 16 different societies; some are for single men, others for public servants, others for factory workers with complicated subdivisions. They may all be united in one great *Cassa*.

The new law raises the wage limit for compulsory insurance from £100 to £125 a year. Therefore, a very large section of the population which paid fees will become contract patients, and the conditions in Germany will come nearer to those that prevail in England. This is distinctly threatening to medical interests. The new law will place under the care of imported doctors at Cologne, and any other city where similar troubles may arise, persons who till now have chosen their own medical attendants, and have been treated, so I am led to believe, with much greater care than they are likely to obtain from any imported staff employed by a *Cassa*. Already and within the £100 income limit there is a large number of insured persons who are very dissatisfied. So much is this the case that, in spite of the smallness of their incomes, they prefer to pay fees to an independent practitioner, and do not call in the insurance doctor. When the insured had, from 1904 to 1909, free choice of a medical attendant they had no need to pay fees. As insured persons they were generally able to secure the services of the medical attendant they preferred.

Lowering the Profession in Germany.

Contract practice, combined with the imposition by the *Cassa* of a doctor chosen by the *Cassa*, does undoubtedly tend to lower the status and aims of the medical profession in Germany, and that is why the more intelligent patients made so vigorous a claim for the free choice of medical attendants. They insisted that doctors should not be employed as the servants of the *Cassa*, but remain free men with patients coming freely to them, a point of view as clear to the medical men in Germany as in this country. The profession look forward to an improvement in the situation because the advantages of the free choice of doctor are becoming more and more appreciated. For another reason the victory may yet incline to medicine. There are signs that the imported doctors may get tired of the position which they occupy and go away. The patients are not contented with a medical attendant who, being secure of his income, has no motive for taking interest in his patients, a feeling which indicates that the bonus system alluded to has borne small fruit. On more than one occasion I have asked German practitioners whether, on the whole, the law on compulsory insurance has helped to raise or has it tended to lower the medical profession. As a result of these inquiries I think it may be said quite decisively that "medical men are not as highly esteemed to-day as they were 30 years ago," and I take these words from the mouth of a highly esteemed Cologne physician, who added that "to-day the insurance doctor is looked upon as an underpaid artisan."

Malingering in Germany.

Then there is in Germany, as in England, the great question of malingering which threatens with financial trouble, that in the weaker cases may lead to bankruptcy, more than one *Cassa*. For in Germany, as in England, this is a real "doctor's dilemma." If he denounces malingering he will be regarded as a hard and impracticable officer by the public, especially if he is a factory doctor, and he may not be re-elected to his post. On the other hand, if he appears to give sick certificates too readily his accessibility will be abused by the public, he will be accused of compromising the finances of his society, and be blamed by the management thereof. Unless the insurance doctors and the management of the societies work harmoniously together this difficulty must arise, but such harmony does exist, I was assured, at Frankfort, Munich, or Leipzig. In those towns, if the doctor was to countenance any form of sickness that was adjudged to be malingering he might be made to pay for the extra expense that had been occasioned. Of course, there must be an expert to act as referee, and all suspicious cases are sent to him either by the *Cassa* or the doctor who has attended the patient. If, further, the *Cassa* and the referees do not work well together there will be serious trouble, for the estimate of a good referee arrived at by a *Cassa* is based upon his powers of protecting the funds. At Cologne much discord has existed on this question. The *Cassa* wanted to use the referees to get a case up against the doctors who are now refusing coöperation, and to show that a free choice of doctor would be too expensive. The referees, in the opinion of the *Cassa*, ought to be constantly condemning the doctors for extravagance, and demonstrating that those who advocated the free choice of doctors were the practitioners who would be unsuitable for the public work. Of course, the referees did not lend themselves to the carrying out of these manœuvres, so they are not on the best of terms with the *Cassa*.

German Pride in Social Legislation.

It is just because the whole system works badly at Cologne that the doctors who have been on strike for five years still look forward to at least a partial victory. At present some of the imported doctors are paid for doing nothing, for insured persons on their lists will not consult them. They prefer to go to a private practitioner and not even say that they are insured. They know that the medical man to whom they pay fees will not pack them off unnecessarily to hospital. For here I may remind my readers that the position in regard to hospitals is quite different in Germany to that which obtains in England. The hospital being a public institution cannot refuse to take in patients. The insurance doctor, when he is paid a fixed salary, saves himself much trouble by sending his patient off to the hospital. But this increases the taxation by augmenting the cost of the hospital. The *Cassa* does not contribute to the maintenance of insured patients in the hospitals. Now the taxpayer is beginning to discover that the imported doctors make greater use of the hospitals than the doctors who are on strike used to do.

---

[1] THE LANCET, Jan. 25th, 1913, p. 257.

The Germans are proud of their social legislation and will see to it that it works properly; therefore, the imported doctors are losing ground in public esteem. It is the boast of Germans that even the poorest, those who are not insured, may always obtain medical advice and the necessary care. There are the doctors of the poor and the hospitals for which no charge is made. Milk, wine, and brandy are forthcoming for the poorest, together with linen, fuel, and whatever else is needed. It is the magistrate who decides what has to be done for those who are ill, are not insured, and cannot pay. The theory is that no one who is ill should be in real want; but this situation costs a good deal, and the public does not desire to see the cost increased because certain medical men send patients unnecessarily to the hospitals. So it comes about that what the organised members of the profession have demanded all along is being gradually recognised as best, not merely for the doctors themselves, but above all for the public at large.

I think that this brief *résumé* of the German position may well be read for its points of comparison with the circumstances in which we now are at home. Similar difficulties are being experienced, and similar remedies are occurring to those interested in various ways. One last comment I must allow myself. The German troubles were perfectly well known to many people before the British legislation was even formulated.

(To be continued.)

KNIGHTWICK SANATORIUM.—The Worcestershire county council has agreed to undertake to provide sanatorium benefit for the insured under an arrangement with the Insurance Committee, and also for the non-insured. The main part of the sanatorium work will be carried on at Knightwick. This sanatorium dates from 1901, when a public meeting was held at Worcester and the Worcestershire Association for the Prevention of Consumption was formed. Mr. James Dangerfield, of Bilston, offered to the association the use of a house and grounds of 29 acres, known as The Agberrows, situated on the Ankerdine Hills, for five years at a nominal rent, with the option of purchase by the association at the end of that time. The offer was accepted, and by means of public subscriptions amounting to £4000 a sanatorium for 16 patients was built and opened in 1902. In 1906 the association purchased the house and grounds at a cost of £6000. In 1902 the county council contributed £300 towards the original building, and the King Edward VII. Worcestershire Memorial Fund produced £4750, which was handed to the trustees for the purpose of enlarging the sanatorium to form a county memorial in memory of the late King. Considerable enlargement is now proposed at an estimated cost of £11,600, towards which is available the memorial fund and £5220 to be received from the Local Government Board, being a grant of £90 per bed in respect of 58 beds. Of the balance of £1630 the county council will pay £1100.

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

BRISTOL AND WESTERN COUNTIES.

University of Bristol.

To the munificent benefactions to the University of Bristol for which the Wills family has been responsible yet another has to be added. Mr. A. Stanley Wills has offered £1000 for the purchase of books which are needed for the library.

Research Defence Society.

In connexion with this society an interesting lecture was recently delivered in the large hall of the Victoria Rooms, Clifton, by Dr. Alice M. Corthorn, whose theme was the cruelty of those who sought to prevent the advance of medicine by agitating for the abolition of experiments on animals. The chair was taken by Dr. J. E. King, head master of Clifton College, who spoke strongly as to the necessity of such experiments. Questions asked by opponents of experimental medicine were replied to by the lecturer.

St. John Ambulance Brigade.

During 1913 the Bristol Corps dealt with no fewer than 12,088 cases, the transport department alone being responsible for 2925. On the day of the King's visit to the Royal Agricultural Show 236 officers, men, and sisters were on duty, over a thousand cases being dealt with.

Gloucestershire Royal Infirmary and Eye Institution.

At the last quarterly meeting of the governors of the Gloucestershire Royal Infirmary Dr. E. Dykes Bower, who had reached the age-limit prescribed by the rules of the institution, gave in his resignation as a member of the honorary medical staff, after having served 22 years as honorary surgeon and 32 years as ophthalmic surgeon. The chairman, Canon Eyre, in accepting the resignation on behalf of the governors, alluded to the valuable services Dr. Bower had given to the charity and announced his appointment as honorary consulting surgeon. It was also unanimously resolved to ask Dr. Bower to continue to take charge of the ophthalmic department.

A Munificent Bequest.

The late Mr. R. Hamlyn Hooker, of Weston-super-Mare, has bequeathed £1000 to the Weston-super-Mare Hospital.

Forty Years of Public Health Service.

Dr. Henry J. Alford has resigned the post of medical officer of health for the Taunton rural district after 40 years' service. The chairman of the rural council, in accepting Dr. Alford's resignation, expressed great regret at the decision, while speaking in high praise of Dr. Alford's services.

Jan. 6th.

SCOTLAND.

University of Edinburgh.

THE annual report of the University for 1913 shows that during the year the total number of matriculated students (including 549 women) was 3261. Of these, 1315 were enrolled in the Faculty of Medicine. Of the students of medicine, 563, or nearly 43 per cent., belonged to Scotland; 231, or year by year. In Paris, where there used to be perhaps 50 cases, there are now 300. This recrudescence appears due to the return home of those who have contracted the disease abroad. Dr. Marchoux, chef de service of the Institut Pasteur, has been directed to report on the question. In his opinion the mode of transmission of leprosy is not yet sufficiently clear, and the only effective measure at present is absolute isolation of the patient, such as was practised in the Middle Ages. Should the family desire it, however, this isolation can be carried out at home under medical supervision. Foreign lepers are not to be allowed to enter France, and those already domiciled there must either submit to the French regulations (at the cost of their country of origin) or be expatriated. The propagation of the disease by rats also demands attention. From his own investigations M. Marchoux affirms that 5 per cent. of the sewer rats are affected. A special commission on leprosy is about to be established at the Ministry of the Interior.

Cerebro-spinal Meningitis.

Cerebro-spinal meningitis has again broken out in France, among the garrison of the 136th Regiment at St. Lô, and at Brest. The first case was found at St. Lô at the end of November. The disease was demonstrated micro-biologically, and treated rigorously. All bacillus carriers, of whom 19 have been discovered, are under observation in hospital. Up to date there have been five cases with one death, all in October recruits. At Brest the first case broke out abruptly at the end of December, and within 48 hours two deaths had occurred. Strong measures are being taken to repress the disease.

The Mechanism of the "Knock-out" Blow.

Dr. Somen advances a theory of the mechanism of the phenomena attending the "knock-out" blow on the lower jaw in boxing. These phenomena have been variously attributed to a sudden displacement of the brain or the cerebro-spinal fluid, or to reflex inhibition. Dr. Somen's theory is that the shock of the blow on the chin is transmitted through the temporo-maxillary articulation to the internal ear, where the disturbance of the semicircular canals gives rise to vertigo, loss of equilibrium and of consciousness. The interference with equilibration is even more pronounced when the blow is received on one side, which accounts for the more severe effect of such a blow over one received in the middle of the chin. Physiological experts, like Dr. Babinski, and medical experts in sports, such as Dr. Heckel, who have themselves experienced the effect of this blow, have approved of Dr. Somen's theory. The dangerous points for the boxer are those whence reflexes take their origin—the epigastrium, from its relation to the solar plexus, and the lower jaw from its relation to the semicircular canals of the internal ear. The anterior surface of the larynx should also be mentioned, a blow on which may induce a fatal reflex, but this blow is ruled out in boxing and is practised only by the apaches, who appear to have imported it from the African Kabyles.

Assistance in Childbirth.

The new law for the assistance of women in childbirth, carried six months ago through the perseverance of Senator Strauss, a member of the Académie de Médecine, came into force on Jan. 1st. Henceforth every woman who claims the benefit of the law must make a declaration in writing, signed by herself or attested by two witnesses, to the mayor of her commune. In the case of those mentally incapable the claim can be made by the mayor with the aid of two witnesses. If the patient is at the time in hospital her claim must be passed by the head of the institution, and must state that she is of French nationality and that she works at her own home or in someone's establishment for a wage. It must indicate her family responsibilities and her resources, especially whatever accrues from her husband's work, during her rest. She must furnish a note showing what contributions she (or her husband) pays, as well as a certificate from her employer stating that she works at a regular wage The mayor forwards these documents after due inquiry to the Bureau d'Assistance, which has the right to institute a control inquiry. This bureau draws up a list of the applicants, the first part containing those who have their families in the commune, and the second those who belong elsewhere This last list is addressed to the prefect by the mayor. The assistance is furnished only for the period preceding or following the particular accouchement for which the application was made and application must be renewed for each confinement. Finally, a medical certificate that a rest period is absolutely necessary and mentioning the approximate date of confinement is required. The date on which the benefit comes into force is fixed by the mayor, but may also be determined apart from him by the prefect. The relief is payable after the confinement, even though the child be born dead. For each assisted woman a person is appointed by the mayor from a list, drawn up a the commencement of each year by the Bureau d Bienfaisance, of persons who are willing to act a inspectors of these patients. At the expiration o the period of assistance this person must state whether the mother has nursed her child at the breast. The benefit can be withdrawn on the decision of the mayor or the prefect if the woman does not conform to the regulations. The amount which is fixed by the Conseil Municipal, is from 1 to 2 francs a day.

Death of an Interne from Typhoid Fever.

M. Théry, a young interne who had charge of the typhoid patients in the service of Dr. Macaigne at one of the Paris hospitals, recently succumbed in eight days to typhoid fever, in spite of the most assiduous attention. During the prodromal stage, while suffering from headache and slight fever of which the cause was not yet recognised, he had the misfortune to prick his hand in making a post-mortem examination. This death has caused no little excitement, in consequence of the campaign now being waged against typhoid fever. M. Théry had not had himself vaccinated against the disease, but it is thought that this occurrence will cause antityphoid vaccination, which is at present optional, to be made compulsory in the *personnel* of the hospitals.

Death of Dr. Louis Jullien.

Dr. Louis Jullien, who has recently died after an illness extending over about 15 years, was a distinguished syphiligrapher. He was an *agrégé* of the Faculty of Lyons, but was settled in Paris, where he was physician to the venereal detention wards of Saint Lazare. He wrote numerous works on venereology and contributed largely to the introduction into France of the treatment of syphilis by injections of calomel.

Jan. 5th

Obituary.

SILAS WEIR MITCHELL, M.D., LL.D.

THE veteran American physician and author, Dr. Weir Mitchell, died at his residence in Philadelphia on Jan. 4th in his eighty-fifth year.

Silas Weir Mitchell, who was the son of Dr. John Kearsley Mitchell, himself an author as well as a medical practitioner, was born in Philadelphia on Feb. 15th, 1829. After a grammar school education he went to the University of Pennsylvania to pursue his classical studies. He took his M.D. degree at Jefferson College, Philadelphia, in 1850, and started the practice of medicine in his native city. During the American Civil War he was placed in charge of a hospital there especially established for the purpose of treating the nervous sequelæ of wounds, and the foundation was thus laid of his future reputation as a nerve specialist. The widely known "Weir Mitchell treatment" in nervous diseases, which consists essentially of rest and complete isolation, is credited to him, and he deserves a full recognition of the fact that he perfected this system, and by his writings and practice led to its adoption in certain conditions. The principles involved had been recognised and followed by many medical men at an earlier period. Among his works on nervous diseases should be mentioned Wear and Tear (1871), Diseases of the Nervous System (1881), and Clinical Lectures on Nervous Diseases (1897). He also made some investigations in regard to snake poisons, anæsthetics, narcotics, and anodynes, and other departments of physiological and medical science. To general literature also Dr. Weir Mitchell made some creditable contributions. He published several novels, of which perhaps the most widely and favourably known is "Hugh Wynne, Free Quaker" (1897), in which he depicts with considerable insight the mental attitude, the life, and manners and customs of the people of his native city at the time of the revolutionary war. His first venture in extra-professional literature which attracted any attention was "Hephzibah Guinness," published in 1880; his last "John Sherwood, Ironmaster," in 1911. He wrote, also, several short stories and some poems, among others "The Masque," a poetic drama, which was staged by the late Mr. Wilson Barrett.

Perhaps the most striking lessons of his work are the evidence it affords that success in no field need be despaired of because it delays its appearance until well on in middle life (for his first really successful novel was published when he was 68) and the compatibility of a simultaneous devotion to both literature and the exacting profession of medicine. Many members of our profession have distinguished themselves in various fields outside of it, but such distinction has for the most part been achieved at the expense of their working interest in medical science. Dr. Weir Mitchell used his literary tastes as a means of diversion only in his leisure.

Dr. Weir Mitchell was a foreign member of the Royal Society, an honorary Fellow of the Royal Medical and Chirurgical Society of London, and honorary foreign Associate of the Académie de Médecine and of the corresponding Swedish and Norwegian Academies. Harvard, Princeton, Toronto, and Edinburgh Universities conferred on him their LL.D. degrees, and the University of Bologna its honorary M.D. He had also been President of the College of Physicians of Philadelphia. He died full of years and honours.

BERTRAM THORNTON, M.R.C.S. ENG., L.R.C.P. LOND., J.P.

Mr. Bertram Thornton died at his residence in Margate on Dec. 28th, 1913, in his fifty-seventh year. He received his medical education at St. Mary's Hospital, London, and at Edinburgh, and qualified as M.R.C.S. Eng. and L.R.C.P. Lond. in 1881. After holding the posts of house surgeon and house physician at St. Mary's Hospital he settled in practice in Margate, his native town, where he entered into partnership with his father, whom he ultimately succeeded. He held many appointments, among them those of consulting surgeon to the Royal Sea-Bathing Hospital, and honorary surgeon to the Margate Cottage Hospital. On his retirement from the staffs of these hospitals he was elected a member of their governing committees, to which his intimate knowledge of hospital requirements and management was of great service, and on which he served till his death. To him was largely due the enlargement of the Margate Cottage Hospital in commemoration of Queen Victoria's Jubilee, a scheme to which he devoted much time and energy, and of which Margate is justly proud. He was also police surgeon, medical officer to the Post Office and the Deaf and Dumb Asylum, and school medical officer.

In public health work he was honourably known. He was medical officer of health for the borough, in which capacity he was associated with the radical changes in the sanitation of Margate, which have made that borough one of the healthiest in the kingdom. He particularly supported the Wingham water scheme, under which Margate now gets its ample supply from 14 miles inland. During the time he served the borough the Town Planning Act was adopted, a refuse destructor erected, infant mortality steadily decreased, and a school clinic was established, in effecting all of which improvements his energy and organising capacity proved of the greatest value. He was, like his father before him, on the commission of the peace for the borough, and served for many years on the town council.

Mr. Thornton's health was undermined by repeated attacks of influenza, which put him on the sick list for months at a time. He leaves a widow and four daughters. He will be greatly missed not only by them, but by his medical colleagues, his patients, and his fellow townsmen, among whom his kindly disposition, sincerity, and unfailing courtesy made him greatly esteemed.

JOHN MEREDITH, M.D. EDIN., L.R.C.P. EDIN., J.P.

Dr. John Meredith, of Wellington, Somerset, died recently at Llandrindod Wells, where he had gone on a visit to his sister. The deceased, who was in his 84th year, received his medical education at Edinburgh University and graduated M.D. in 1861, having taken the L.R.C.S. Edin. the year previously. After holding resident appointments at the Edinburgh Royal Infirmary, the Morningside Asylum, and the General Hospital at Demerara, Dr. Meredith commenced practice at Wellington, where he soon obtained a large connexion. He was for many years medical officer of health for the urban district, medical officer to the workhouse, and certifying factory surgeon. He took a great interest in all local matters, and for about ten years represented Wellington on the Somerset county council. He was a magistrate for the county, and surgeon-lieutenant-colonel of the 2nd V.B. Somerset Light Infantry, V.D. (retired). Dr. Meredith will be much missed in Wellington and the district, for he was greatly respected.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Warren O. Plimpton, formerly professor of surgery in the New York Post-Graduate School and Hospital.—Dr. L. Ewer, of Charlottenburg, Sanitary councillor. —Dr. O. Kessler, of Berlin, Sanitary Privy Councillor.—Dr. Louis Jullien, formerly surgeon to the St. Lazare Hospital, Paris.—Dr. G. Vignier, professor agrégé of parasitology in the Algiers Medical School.—Dr. Elie Faivre, formerly physician to the Lyons Hospitals.—Dr. G Juffinger, extraordinary professor of otology and laryngology in the University of Innsbruck, aged 60.—Dr F. Krug, senior staff surgeon of Munich.—Dr. Pascual Gentile, of Buenos Aires, an Italian graduate who was looked upon as an authority on malarial fevers.—Dr. Camille De Clerco, president of several of the medical and scientific societies of Ghent.—Dr. Ernest Snoeck, honorary president of the Belgian Provincial Medical Commission.

Correspondence.

"Audi alteram partem."

THE RESPONSIBILITY OF THE MEDICAL PROFESSION AS REGARDS ANTI-TYPHOID INOCULATION.

To the Editor of THE LANCET.

SIR,—As a worker in the tropics in the ubiquitous position of a civil surgeon, and one therefore who has to deal with almost every variety of patient and disease, I would like to make a most urgent appeal and protest to all medical men in Great Britain.

It has been my fortune to deal with many new arrivals in the tropics, including officials, missionaries, business men, &c. Many of these have come or been sent by their superiors to be inoculated against typhoid. Others, when I have asked them if they have been inoculated, have said, "My doctor at home does not believe in anti-typhoid inoculation and thinks it useless." This latter statement by a professional brother ignorant of tropical work and conditions thrown at the head of one who has seen so many terrible tragedies from the want of inoculation makes it imperative that I should protest as publicly as possible against what I can only consider as loose talk and the want of realisation on the part of the medical man as to how some patients take in, dwell on, and misconstrue any general statement made by a doctor. Unfortunately, the terrible responsibility of the above (to me wicked) advice cannot be brought directly on to the head of him who gave it, when these tragedies occur. Talking this matter over with my friends in the Royal Army Medical Corps stationed here, they have assured me that my experience is not unique, and that they also have come across many such cases.

In conclusion, I would ask any medical man who is a sceptic as regards the value of antityphoid inoculation to study the statistics issued by the Royal Army Medical Corps, and those of the Director General of the United States Army Medical Department. I am also sure that the Director of the Royal Army Medical College, Millbank, would supply information to any one really interested in knowing the real truth.

I am, Sir, yours faithfully,
C. MADDOCK, M.D. Edin., F.R.C.S. Edin.,
Major, I.M.S.
Ahmednagar, India, Dec. 19th, 1913.

"THE DANGERS OF STERILISED MILK."

To the Editor of THE LANCET.

SIR,—The line printed above this is the heading of an important article in the *Times* of Dec. 29th, in which Mr. Robert Mond had a good deal to say against the practice of sterilising the cow's milk on which children are fed. The heading may possibly have surprised or even alarmed some people; others it may have pulled up short and caused them to think, for sterilisation of children's milk is still widely believed in as necessary. It is, indeed, part of the ritual of most nurseries.

The question of the expediency or the necessity of the practice, however, cannot conveniently be entered into by medical men in the public press (though I for one am grateful to the *Times* for bringing the matter forward, as well as for the way in which it has been done), and I hope that THE LANCET will be inclined to open its columns to a discussion on the subject.

I do not know when the sterilisation of nursery milk was first advised, but it is easy to see how it came about. Thus, cows are liable to tuberculosis; milk from a tuberculous cow may give rise to tuberculosis in the human subject; the germs of tuberculosis are killed by a heat somewhat below that of boiling water; children may be fed on milk thus treated without risk of their being infected with the germs of tuberculosis, even if the milk be drawn from tuberculous cows. It is very simple and attractive.

But we do not yet know for certain that milk from a tuberculous cow will infect a human being. Mr. Mond says that children have been reared on unsterilised milk from cows which have afterwards been found to be tuberculous, and have been none the worse for it. He also reminds us that our post-mortem records reveal the fact that tuberculous children are infected by the air-passages rather than by the stomach or bowel. He also tells of certain kittens which, being fed wholly on sterilised cow's milk, died miserably; whilst others, used as a control and fed on plain cow's milk, grew up and flourished. This was a valuable vivisection experiment, and it is to be hoped that by planning it and seeing it carried out, Mr. Mond will not have attracted the suspicion or violence of any of his friends.

Of the biochemistry of the sterilisation of milk I am not competent to speak, but I do know this, that during the process it has been strangely altered, for its taste is quite different. The milk has been changed from a living fluid to a dead one. To the adult this may not signify much, but for the child it may make all the difference, the milk having lost its *living spirit*. What exactly this living spirit of milk may be the chemist is unable to tell us. At any rate, he cannot separate it in his test-tube nor weigh it in his most delicate balance. Yet it exists. Perhaps the physiologist, who is less of a materialist, can make a guess as to its nature. Otherwise it must be left to the medical man to predicate concerning it.

My own opinion is that sterilisation renders cow's milk unsuitable as a food for young children. I am half inclined, indeed, to use the word *dangerous.* I have closely watched infants whose only food has been sterilised cow's milk, and have found many of them poor and ill-nourished, and just in the con*dition to fall victims to tuberculosis. Later on*, I have detected in them the early signs of rickets. In others I have found the tender bones and the spongy or bleeding gums of scurvy. But as soon as the sterilisation of the milk was stopped improvement set in and was continued.

I am, Sir, yours faithfully,
EDMUND OWEN,
Consulting

Upper Berkeley-street.

*** When Mr. Owen says that "we do not yet know for certain that milk from a tuberculous cow will infect a human being," we must point out that certain knowledge of a negative event is almost impossible to come by. All the admirable work done for the recent Royal Commission on Human and Animal Tuberculosis, and the recommendations of that Commission, support the view that infection of the human subject by the tuberculous cow can and does occur — ED. L.

ON THE PATHOLOGY OF RHEUMATOID ARTHRITIS.

To the Editor of THE LANCET.

SIR,—Two articles have recently appeared in THE LANCET which seem to me to have an important bearing on the etiology and pathology of rheumatoid arthritis. One, an annotation headed "Periarthritis after Herpes Zoster,"[1] the other on "The Primary Cause of Rheumatoid Arthritis," by Dr. H. Warren Crowe,[2] and I shall be obliged if I may, as briefly as possible for the present, point out their significance.

In the annotation reference is made to a case reported by M. Georges Guillain and M. Daniel Routier to the Société Médicale of Paris on Oct. 31st, in which chronic periarthritis of the hand followed herpes zoster of the dorsal aspect of the left hand and of the forearm, the eruption, *associated* with continuous pain and stiffness of the finger-joints, lasting 15 to 18 days, and for a long time afterwards there was *œdema of the hand.* When the pain ceased the stiffness of the joints remained, and the hand could not be used. After two years there was some improvement, but the hand could not be shut. Further details are given, and reference is made to other cases reported by M. Guillain and M. Pernet in 1910, and M. Claude and M. Velter in 1911, of "zona of the upper limb followed by *lesions resembling* arthritis deformans."

Now these cases seem to me to illustrate and confirm in a remarkable manner the view which I have held for many years that the progress of arthritis deformans is associated with and dependent upon irritative or destructive lesions of the anterior cornua of the spinal cord, the lesions being especially marked in the cervical and lumbar enlargements.

According to von Bärensprung, *zona is* the result of inflammation of the intervertebral ganglion on the root of the nerve from which are derived the branches distributed to the part of the skin on which the eruption appears. The ganglion is found to be swollen, congested with blood, softer and redder than natural. The blood-vessels are engorged, and the tissue under the microscope exhibits minute hæmorrhages which press upon and destroy the ganglion cells. The researches of Head and Campbell also indicate that the disorder is associated with hæmorrhages and *inflammatory foci in the ganglia of the posterior* roots, with destruction of the ganglion cells of the nerves supplied to the affected part.

It is not unreasonable to assume that in some of these cases the irritation caused by the inflammatory or other changes in the ganglion cells of the posterior roots may give rise to changes in the ganglion cells of the anterior horns and in the anterior nerve roots; in the same way as irritation of the peripheral end of afferent nerve fibres by reflex action will cause a nervous stimulus to pass along the efferent fibres proceeding from the anterior cornua. In this way the nutrition of the muscles, bones, and joints over which the ganglion cells of the anterior horns are supposed to exercise a controlling influence will be modified and produce the changes associated with rheumatoid arthritis in the limb to which the affected nerve is distributed.

On these grounds I urged 12 years ago[3] that the most effective treatment of rheumatoid arthritis is by blistering the spine, especially in the regions of the lumbar and cervical enlargements of the cord, and consequently I think that, in the case reported by M. Guillain and M. Routier, the careful application of cantharides ointment on each side of the seventh cervical vertebra would have been followed by a marked decline of the arthritic trouble. Of course, as the patient suffered from diabetes more than ordinary care would be necessary in applying the counter-irritation. Full details as to carrying out this plan of treatment are given in the Proceedings of the Royal Society of Medicine, May, 1910 (Balneological Section), p. 109.[4]

Dr. Warren Crowe's paper on the Primary Cause of Rheumatoid Arthritis is, I venture to say, one of the most important and suggestive that have lately appeared on the subject. The fact that in almost all cases he has been able to discover and isolate a new streptococcus in the urine bearing a close relationship to micrococcus epidermidis, and that the administration of a vaccine prepared from this *to individuals suffering from rheumatoid arthritis* has been followed by the relief and cure of the disease, is very strong evidence that there is some relationship between the streptococcus and the disease, more especially when similar beneficial results have been obtained by other observers.

But the question immediately suggests itself, In what way does the avirulent micrococcus epidermidis of the skin acquire pathogenic power? With all due reserve I venture to suggest that it arises from the presence in the blood-stream of the products of imperfect metabolism of the muscular and other tissues; and that this imperfect metabolism is due to changes in the circulation resulting from irritation in various parts of the body of the afferent nerves, and so bringing into play the action of the vaso-motor nerves, as may be illustrated by the effects resulting from section of the sciatic nerve, and irritating the peripheral end. Division of the sciatic nerve causes dilatation of the small arteries of the foot and leg, whereas irritation of the peripheral end of the divided nerve gives rise to constriction, the effect varying according to the interval which has elapsed after section of the nerve. Irritation of any sentient part of the body will induce an afferent impulse ascending by the posterior roots of the nerve through the spinal cord to the brain, and cause a reflex and efferent impulse to descend along those fibres of the cord which pass out by the anterior cornua and anterior roots of the nerve. These contain both motor and vaso-motor fibres, and by the action of the latter there will be constriction of the small arteries, a diminished supply of blood, and consequently of oxygen, to the part, and as a result imperfect oxidation and imperfect metabolism of the tissues, morbid substances being formed and passing into the blood to be eliminated by the various excretory organs. If not excreted it is conceivable that the avirulent micrococcus epidermidis cultivated in such a medium may undergo some change in its constitution, become pathogenic, and present the characters of the micrococcus deformans, the toxin of which may irritate the afferent nerve fibres or the posterior roots and so develop the changes (or intensify pre-existing ones) in the ganglia of the anterior cornua, upon which I believe this disorder depends.

[1] THE LANCET, Nov. 29th, 1913, p. 1560.
[2] THE LANCET, Nov. 22nd, 1913, p. 1460.
[3] THE LANCET, April 6th, 1901, p. 1000.
[4] THE LANCET, Sept. 24th, 1910, p 927.

I hope before long to develop this view more fully. If the theory is true it is applicable also, with some modifications, to acute rheumatism and gout, but, most important of all, it indicates how in some measure an avirulent microbe may become pathogenic.

Upwards of 30 years ago Sir James Paget wrote: "Disturbances in the nervous system in some part and form may be regarded as a factor in every case of gout. There are reasons enough for thinking that changes in the nervous centre determine the locality of each gouty process, while changes in the blood and tissues determine its methods and effects: and that thus we may explain the symmetries of disease in gout—sometimes bilateral, sometimes antero-posterior—and thus its metastases." This quotation, I hold, is equally applicable to the pathology of acute rheumatism and of rheumatoid arthritis.—I am, Sir, yours faithfully,

P. W. LATHAM.

St. James' Court, Buckingham Gate, S.W., Dec. 30th, 1913.

BIG GAME AND SLEEPING SICKNESS VERSUS MAN AND HIS ANIMALS.

To the Editor of THE LANCET.

SIR,—In reference to Dr. Warrington Yorke's letter in THE LANCET of Jan. 3rd I quite agree as to Taute's experiment that no generalisation should be made from one fact. My phrase "goes to prove" was not intended to mean this. To be more explicit, allow me to enlarge it thus, "tends to prove for what it is worth," and this it certainly does. Dr. Yorke says that this experiment shows that healthy human beings are able to a great extent to resist infection, and later that the disease has proved invariably fatal. Do these two statements lie comfortably alongside each other?

Considering all the points raised I am at a loss to understand why the would-be slaughterers of the game cannot be satisfied with an experiment over a fenced area of a few square miles, instead of a general massacre by the natives and others that is advocated. Such an experiment would be likely to teach us a great deal if the money could be found.

I am, Sir, yours faithfully,

Harley-street, W., Jan. 3rd, 1914. SHEFFIELD NEAVE.

THE CENTENARY OF SIR JAMES PAGET.

To the Editor of THE LANCET.

SIR,—I think it will interest your readers to learn that as Sunday next, Jan. 11th, is the centenary of the birth of Sir James Paget, the occasion is being specially commemorated in the parish church of Great Yarmouth, with which Sir James Paget and his family were intimately connected. His son, the Bishop of Stepney, is preaching throughout the day, and the morning service will be attended by the mayor in state and the aldermen and councillors of the borough, the naval and military forces stationed in the town, and by a body of doctors and nurses. There will also be present the Master of Downing, Professor of Surgery in the University of Cambridge, and delegates from the Norwich Medical Association and from several scientific societies.

I am, Sir, yours faithfully,

C. LISLE CARR,

Yarmouth, Jan. 6th, 1914. Vicar of Great Yarmouth.

THE GENERAL MEDICAL COUNCIL AND APOTHECARIES' HALL OF IRELAND.

To the Editor of THE LANCET.

SIR,—My Board having taken the view that the recent action of the General Medical Council in transmitting charges against the Apothecaries' Hall to the Privy Council was unconstitutional, beg to enclose for your information the following letter from the Privy Council.

I am, Sir, yours faithfully,

HENRY W. MASON, L.R.C.S.I.,

Mary-street, Dublin, Jan. 2nd, 1914. Registrar.

[COPY OF LETTER RECEIVED FROM PRIVY COUNCIL, JAN. 1ST, 1914.]

The Clerk of the Council, Privy Council Office,
London, S.W., Dec. 31st, 1913.

SIR,—Referring to your letter of the 22nd inst., I have to state that no useful purpose would be served by submitting to the Lords of the Council the reply of the Apothecaries' Hall of Ireland to certain charges made by the General Medical Council, since the matter in question is not before their Lordships.

I am, Sir, your obedient servant,

The Secretary, Apothecaries' Hall of Ireland, Mary-street, Dublin. ALMERIC FITZROY.

A PROPOSED PRIVATE HOSPITAL.

To the Editor of THE LANCET.

SIR,—A good deal of attention is now being directed to the question of private surgical or medical homes for the middle classes, and it is likely that increasing attention will be devoted to the subject in the near future.

In his letter on the subject in your issue of Jan. 3rd, with the above title, Dr. A. B. Bradford states that the remedy required at the present time is to build a large central private hospital for paying patients—to establish, in fact, a hotel for sick people in place of the existing lodging houses. He further indicates that it must be centrally situated in order to be convenient to patients and medical men, and it must be capable as to price of housing all a medical man's cases who can afford fees; and, as far as accommodation goes, must begin where the hotel has left off, and not where the hospital has stopped.

It may be of interest to Dr. Bradford and to others interested in the subject to know of the existence of the Queen Mary Nursing Home in inburgh. This institution was planned to give ;ients of moderate means the comforts, appli- :es, and conveniences which are provided ıtuitously at hospitals for the poor. It contains beds, and its development was made possible 'the coöperation of the medical profession and ; public. It is not run for profit and is intended be self-supporting. It is arranged to admit cases ying at the rate of from £1 1s. per week for board d nursing to £3 3s., patients paying the latter only having a room to themselves. Previous perience of a similar home run on a small scale d justified the belief that such a home could be f-supporting, and it is gratifying to find that as a sult of its first six months' working there is a very bstantial balance on the right side.

The Queen Mary Home has already attracted nsiderable attention, having been visited by ıny medical men and others interested from her centres. The correctness of the principle ıderlying the establishment of this home may be garded as established, and it is probable that, ike in the interests of the profession and of the blic, an extension of such a scheme will be dely adopted in the future.

I am, Sir, yours faithfully,

CHALMERS WATSON.

dinburgh, Jan. 5th, 1914.

[HE PHOSPHORUS CONTENT OF RICE.

To the Editor of THE LANCET.

SIR,—I am at present having to deal with an)idemic of beri-beri in the British regiment at this ation. The disease, so far as can be found out, ıs not been described as occurring in the Sudan fore.

In the course of investigations as to the possible .use attention has been paid amongst other things the rice, though that is not regarded as the prob-)le cause of the present outbreak, as rice is not a rge constituent of the soldiers' food.

On referring to an article on the subject in your sue of July 26th, 1913, p. 236, an annotation on)ri-beri in Siam and the work of Dr. H. Campbell 'ighet and others, I find the following statement: 'The phosphorus content of a rice should not be ss than 4 per cent., and this should be taken as e indicator of the safety or otherwise of the rice." The figure mentioned is obviously a typographical ror, and I should be much obliged if you would ıdly inform me what the correct figure is.

Dr. Beam, research chemist at the Wellcome)ical Research Laboratories, has kindly analysed me the rice issued to the troops here, and his re for phosphorus is 0·13 per cent. This rice is ordinary polished rice.

I am, Sir, yours faithfully,

A. D. STIRLING,
Captain R.A.M.C.

lah Barracks, Khartoum (Sudan),
Dec. 27th, 1913.

* We regret very much to have overlooked the obvious rint. The figure should have been, as Captain Stirling orrectly surmised, 0·4.—ED. L.

THE ATROPINE TREATMENT OF SEA-SICKNESS.

To the Editor of THE LANCET.

R,—*Apropos* the advocacy of atropine in sea- ness by Fischer, alluded to last week in an)tation in THE LANCET, I should like to say I have found the hypodermic injection of)hate of atropine to be the most reliable cure ıea sickness I have ever tried. In 1906, when)lling for my health as surgeon in charge of a liner, I met an American physician who told me of this remedy, and I can strongly support Fischer's opinion as to its value. The milder cases do not often come under the notice of the surgeon, whose time is pretty fully occupied when in charge of from 1500 to 2000 people, and who has to act as surgeon, physician, bacteriologist, anæsthetist, and sometimes nurse. When called to a bad case of sea-sickness my plan was to give one-hundredth part of a grain of atropine sulphate hypodermically and repeat if necessary in an hour or two; often the sufferer would sleep a few hours, possibly because he had been without sleep for some time, and would then come up on deck and have no return of the sickness. I can endorse Fischer's opinion that relapses were not common and that one injection frequently cured.—I am, Sir, yours faithfully,

REGINALD POLLARD, M.B. Durh., D.P.H., &c.

South Kensington, Jan. 6th, 1914.

INSTRUCTION IN THE NATURE OF ALCOHOLISM.

To the Editor of THE LANCET.

SIR,—May I ask you for space to endorse emphatically Dr. Hugh Wingfield's appeal for instruction for the rising generation of medical practitioners on the nature and proper treatment of alcoholism? It is essential that old and provedly erroneous theories as to cause and treatment of delirium still to be found in medical text-books should cease to be taught, and the more modern and proved theories taught in their place. If alcoholism and its victims are to receive proper attention, which they are not getting at present, the nature of alcoholism must be understood, as at present it most emphatically is *not*, by the bulk of general practitioners. The differential diagnosis between dipsomania, pseudo-dipsomania, and chronic alcoholism must be understood and the treatment appropriate to each applied. Lastly, the profession must be taught, in order that they may in turn teach the laity, that this or that combination of drugs, while good so far as it goes in selected cases, or mere isolation from alcohol with or without drugs, while also of benefit so far as it goes, is not, without psychic treatment in its widest sense, sufficient or efficient treatment of alcoholism; and that imprisonment or the infliction of fines (the latter usually paid by long-suffering friends and relations) for drunkenness is as harmful as it is futile.—I am, Sir, yours faithfully,

J. W. ASTLEY COOPER, L.R.C.P. Edin.,
Medical Superintendent, Ghyllwoods Sanatorium, near
Cockermouth, Cumberland.

Jan. 5th, 1914.

THE NATIONAL INSURANCE ACT: THE SURPLUS FUND.

To the Editor of THE LANCET.

SIR,—As the panel practitioners have evinced considerable interest since the publication of my letters to the press *re* the disposal of the so-called surplus fund, they would, I believe, like to learn whether I have any further developments to announce.

1. Mr. Dawes, the chairman of the London Committee, writes to say that he has no authority to accept any legal notice on behalf of the Committee, but that all formal communications should be addressed to the clerk of the committee.

2. The chairman of the London Panel Practitioners' Committee writes as follows:—

I may say that our committee do [illegible] that the doctors who accepted insured persons [illegible] paid in full, and I can assure you that we shall see that this is done. We also intend to submit a scheme for the equitable distribution of the unallotted residue.

3. Dr. Beaton has also sent me a letter which, although not confidential, contains matters of a controversial nature (other than the main point at issue), in regard to which I have asked him to defer the discussion till after the panel doctors have been paid their legitimate dues, when the unallotted residue alone will remain to be dealt with. I am, Sir, yours faithfully,

Tooting, S.W., Jan. 5th, 1914. EDWARD NUNDY.

*** Previous communications from Mr. Nundy are referred to in another column (p. 149).—Ed. L.

DISLOCATION OF THE PROXIMAL PHALANX OF THE GREAT TOE.

To the Editor of The Lancet.

Sir,—In an annotation in The Lancet of Jan. 3rd on the subject of dislocation of the proximal phalanx of the great toe this lesion is described as one of extraordinary rarity. It may therefore possibly interest those who have collected or may be about to collect statistics on this dislocation to know that an instance of it is recorded in the surgical registers of St. George's Hospital for April, 1904, under the distinguishing number 696 S.R. The injury was sustained in a fall from a wall, and the patient died a few days later from head injuries sustained at the same time.—I am, Sir, yours faithfully,

Henry Robinson, M.D. Cantab.

Brechin-place, S.W., Jan. 5th, 1914.

THE NATIONAL INSURANCE ACT.

Medical Benefit and the New Year: the Card System.

In response to numerous medical representations that insured persons should be provided with vouchers, the English Insurance Commissioners have adopted a Medical Card system which is described in a leaflet (Memo. 189/I.C.). Besides affording a ready means of identification of his panel patients by a practitioner without the necessity of examining his card index list, the voucher provides an opportunity for imparting to insured persons information and instructions as to the procedure necessary for obtaining medical benefit and the rules which must be observed. The Commissioners anticipate that the Medical Card system will facilitate the work of medical practitioners and the administration of medical benefit generally; while it should assist Local Insurance Committees to secure more accurate registration of the insured persons in their area and consequently more equitable remuneration of practitioners. Approved Societies will probably avail themselves of it for the purpose of informing their members that red medical tickets and forms Medical 32 are no longer available for the purpose of choosing a doctor or institution and will not be accepted. The new medical card is in itself a document which will require a good deal of study before the insured person masters its details, but will be found when duly studied to provide for all the more likely contingencies.

The card is of buff colour. It is a double fold card, measuring $4\frac{5}{8}$ inches by $3\frac{7}{16}$ inches when doubled, and contains on the front page blank spaces for written particulars of the insured person and the name of the medical attendant. The second page contains general instructions. The third page contains blank forms of application to be placed on a selected practitioner's list by an insured person who has hitherto failed to make his choice or has moved into another district, together with spaces in which the practitioner can indicate that he intends to claim for mileage or to supply drugs. On the fourth page is a summary of the rules as t the conduct of insured persons in relation to thei medical attendant, also a form of application fo medical treatment during temporary residenc away from home, and a space for the signature of the practitioner agreeing to give such temporary treatment. Thus there are spaces to be made use of: (*a*) when the patient is no on the list of a doctor and wishes to choose one (*b*) when he has removed altogether to a new address and therefore cannot get treatment from the medical man named on the front page; (*c*) when he is temporarily residing in a new locality where he does not expect to remain for as long as three months from the date of his arrival. Circular 41/I.C. accompanying the card gives the information that the latter is to be obtained by new entrants to insurance on receipt by the Insurance Committee from the society of the index slip relating to the member. Persons already insured who have not chosen their medical man can get their medical cards by filling form Medical 50, and sending it to th Insurance Committee. Insured persons already o the list of a medical man will be furnished wit medical cards by the Insurance Committee "in du course." When once an insured person has got his card he must be prepared to produce it to the medical man whenever treatment is required. Form Medical 50 has been referred to above; it has been issued simultaneously with the medical card and will require equally careful study before it is filled up by those whom it concerns. Circular 41/I.C contains full particulars, besides those mentioned, as to the steps to be taken in connexion with the new system of Medical Cards, and also contains explanations and instruction relating to the obtaining of medical and sanatorium benefit by insured persons aged 65 or over on entry into insurance.

A particular Medical Card will enable the insured person to obtain treatment during temporary residence in one area only and from one doctor. O and after Jan. 12th next no insured person will be able to exercise choice without a Medical Card, and medical men should, therefore, not accept insured persons failing to present duly completed cards The cards of patients accepted by him, whe properly filled in, should be retained and signed b the practitioner and forwarded to his Insura Committee. He should not take the Medical Car of those whom he does not accept or who has failed to complete their cards. When the system in full operation a practitioner on giving tre will be entitled to require presentation of the Medical Cards by insured persons.

Exempt Persons' Benefits.

The National Health Insurance Joint Committe acting jointly with the Insurance Commissione and the Welsh Insurance Commissioners, ha issued regulations to come into operation diately under the title "National Health Insura (Exempt Persons' Benefits) Regulations, 1913 Exempt persons are those holding certificates exemption under Part I. of the principal Act, a the benefits to which they are entitled are medic benefit and sanatorium benefit. Exempt persons in respect of whom not less than 20 contributions have been paid are entitled to the benefits, those making application to the Commissioners becoming so entitled six weeks after the date of their application and those not so applying at the commencement of the "benefit period" next after the end of the "contribution period" in which the twentieth contribution was paid in respect of them. Contributions paid in respect of exempt persons are to be carried by the Commissioners to an Exempt Persons' Fund, and provision is made for the transference of various amounts from this fund to the General Medical Benefit Fund, the General Medical Benefit Administration Fund, and the General Sanatorium Benefit Fund. Financial provision is made for the case of exempt persons entering into insurance as employed contributors and for securing sickness benefit for them.

THE COMPLIMENTARY DINNER TO DR. CHRISTOPHER ADDISON, M.P.

The dinner to Dr. Addison, M.P., at which the Chancellor of the Exchequer will preside, will be held at the Trocadero Restaurant on Tuesday, Feb. 3rd. The following have joined the committee:—Lord Sandhurst, Sir Clifford Allbutt, Sir Arbuthnot Lane, Sir Almroth Wright, Sir Victor Horsley, Sir Robert Philip, Sir Shirley Murphy, Colonel Sir William Leishman, the *Right Hon.* R. Farquharson, M.D., Professor Sims Woodhead, Professor Keith, Professor Arthur Thomson, Professor William Wright, Professor A. M. Paterson, Professor William Bulloch, Dr. F. W. Mott, Dr. Arthur Latham, Mr. Lenthal Cheatle, Mr. C. J. Bond (Leicester), Dr. Ewen Maclean (Cardiff), Dr. Adam Fulton (Nottingham), Mr. D. F. Todd (Sunderland), Dr. Buist (Dundee), Mr. C. E. Fleming (Bradford-on-Avon), Dr. Norman Walk

siderable number of Dr.

colleagues. Tickets for

excluding wine) should be applied for without delay. They can be obtained from Sir John Collie, 25, *Porchester-terrace*, W., and Dr. H. H. Mills, 21, St. Mary Abbots-terrace, Kensington.

CERTIFICATES SIGNED BY MEDICAL MEN NOT UPON PANELS.

The Non-Panel Committee of the British Medical Association has issued a circular calling attention to the mistaken idea held by many insured persons that they can only obtain payment of sickness benefit by producing the certificate of a medical man on the panel. That this is not the law was decided by the Court of Appeal in Heard *v.* Pickthorne, and any insured person who chooses to be attended by any medical man whom he may select is entitled to do so. He is not then entitled to obtain his medical man's fees or payment for his medicine out of the insurance funds, unless, of course, he is being attended by a non-panel medical practitioner after having obtained the permission of the Insurance Committee to make his own arrangements. He is, however, entitled to the other benefits, including sickness benefit, and to obtain the latter by producing the proper certificate signed by a medical practitioner, whether on the panel or not. It is to the interests of medical men not on the panel, and of their patients, that the above should be clearly recognised, not only by the insured, but by members of Insurance Committees, who are stated to be in some cases under the impression that persons permitted to make their own arrangements will not be able to obtain sickness benefit upon the certificates of the practitioners whom they may select.

A SUGGESTION AFFECTING PART OF THE SURPLUS FUNDS.

Mr. E. Nundy, a medical man on the panel and a barrister, makes a suggestion with regard to the surplus funds accumulated through the failure of insured persons to select their medical attendants, which may be summarised as follows. Mr. Nundy is of the opinion that a very large proportion of the London insured who did not select their medical attendant at the beginning of 1913 did so in the course of the year and that any medical man so selected ought to have been credited with a full year's fees in respect of each patient coming on to his list during the year in whatever quarter he may have been accepted as such. This view does not, of course, affect the case of patients who made no selection in the course of the year, but with regard to those to whom it does apply Mr. Nundy suggests the bringing of a friendly action with a view to establishing the legality of payment upon the principle which he advocates. It happens, however, that the mode of payment actually adopted was in accordance with the Administration of Medical Benefit Regulations, 1912, Schedule I., Part II. A, and Mr. Nundy asks that the London Insurance Committee in defending the action which he proposes should not rely upon this part of the schedule. He further urges that its significance was so misunderstood by medical men who outwardly assented to it when they went upon the panel, that their agreements in respect of it would not be binding upon them. We confess that we do not see how defendants to an action, friendly or otherwise, could start by failing to plead the regulation under which they acted when the legality of their proceedings is the point for consideration, and we are a little doubtful as to whether the schedule referred to is quite as obscure as Mr. Nundy declares. In comparison with some paragraphs in the new regulations it strikes us as lucid rather than otherwise. It appears, however, from a letter which we publish this week from Mr. Nundy that the chances of any such action being brought are rather remote.

THE COST OF DRUGS AT ABERDEEN.

At Aberdeen comment has been made upon the fact that the cost of drugs per head under the National Insurance Act has been 1*s.* 11*d.*, as against 1*s.* 10*d.* at Dundee and Inverness and lower figures elsewhere. The chemists on the panel approve these figures, and incidentally pay a compliment to the medical practitioners in their city by arguing that a low drug bill means the cheapening of prescriptions at the expense of the patients. The medical men, they contend, have sacrificed their own interests—i.e., their chance of receiving the "floating sixpence"—by prescribing the best medicines for their insured patients. The *Aberdeen Journal* refers to this as an explanation "reflecting the highest credit on city medical men."

NEW MEDICAL OFFICERS ON THE STAFF OF THE ENGLISH COMMISSION.

In connexion with the posts of medical officer on the staff of the National Health Insurance Commission (England), for which applications were recently invited, the Insurance Commissioners announce that they have made the following appointments:—Edward William Adams, M.D. Lond., lecturer in materia medica, pharmacology, and therapeutics, and internal examiner in materia medica and pharmacology in the University of Sheffield; James Pearse, M.D., C.M. Edin., medical officer of health of Trowbridge urban district council; William Vernon Shaw, M.A., M.D. Oxon., medical officer of health to Malton and Norton (Yorks) rural district councils; and Barbara Martin Cunningham, M.D. Edin., D.P.H. Camb., resident medical officer at Clayton Vale Hospital, Manchester. Dr. Adams, Dr. Pearse, and Dr. Vernon Shaw are also engaged in private practice.

Medical News.

University of London.—Advanced lectures in medicine have been arranged for the second term as follows: (1) A lecture on Apraxia: its Clinical and Localising Values, by Dr. S. A. Kinnier Wilson, at University College Hospital Medical School, at 4.30 p.m., on Thursday, Jan. 29th; (2) a lecture on the Action of Radium upon Animal Cells, by Dr. H. Beckton, at Middlesex Hospital, at 5 p.m., on Wednesday, March 4th; and (3) two lectures on the Pathological Excretion of Nitrogen by the Skin and the resulting Changes in the Urine, by Dr. H. L. Tidy, at the London Hospital, at 4.30 p.m., on Wednesdays, March 4th and 11th. The following lectures will be given during the third term: One lecture on Recent Observations on Ulcers of the Stomach, by Dr. Charles Bolton, at University College, and three lectures on Carbohydrate Metabolism in Health and in Diabetes, by Dr. H. MacLean, at St. Thomas's Hospital. The lectures are addressed to advanced students of the University and to others interested in the subjects dealt with, and admission will be free. A course of 12 lectures on the Protozoa Parasitic in Man will be given at the Lister Institute of Preventive Medicine, Chelsea, by Professor E. A. Minchin, professor of protozoology in the University, on Tuesdays and Fridays during the second term at 5 p.m., beginning on Tuesday, Jan. 27th. Each lecture will when possible be followed by exhibits of microscopic preparations illustrative of the subject of the lecture. Beginning on Jan. 15th a course of eight or nine University lectures on Anaphylaxis will be given free at King's College Department of Bacteriology, 62, Chandos-street, by Dr. L. Rajchman (Cracow), at 5 p.m.—A course of lectures and practical instruction on Physical Anthropology will be given in the department of anatomy of University College by Dr. D. E. Derry, lecturer in physical anthropology. The course will comprise one lecture and two meetings for practical work each week from Jan. 15th to March 20th. The following branches of the subject will be dealt with: Cranioscopy, craniometry, osteometry, anthropometry (on the living subject), estimation of stature, age, and sex from bones, comparison with higher mammals, especially the anthropoid apes, and race distribution and characteristics. The fee for the course is £2 2s.; to graduates and regular students of the University it is £1 1s. Applications should be made to the secretary, University College, London.

Donations and Bequests.—The Cancer Hospital, Fulham, will benefit under the will of the late Mr. T. Cuvelje by a sum of nearly £70,000. To the Surgical Aid Society the testator left £5000, and a like sum to the Royal Hospital for Incurables, Putney.—The late Miss E. M. Easton has left by will £10,000 to the Durham College of Medicine.—By the first distribution of the residue of the estate of the late Mrs. M. B. Swaine, £4600, St. George's Hospital will receive £1000, the Hastings and East Sussex Hospital and the Guest Hospital, Dudley, £250 each; and the Corbett Hospital, Stourbridge, the Royal Victoria Hospital, Folkestone, the Middlesex Hospital, Hospital for Women, Soho-square, the London Hospital, the Metropolitan Free Hospital, the Charing Cross Hospital, the Evelina Hospital, the Queen's Hospital for Women, and the Lock Hospital, £200 each.—The late Mr. Arthur Paton Matthewson, of Dundee, has left £250 to the Dundee Royal Infirmary, £250 to the Royal Victoria Hospital, Dundee, and £100 to the Dundee Sick Poor Nursing Society.—By will the late Mr. Leonard Dingley, of Bournemouth, left £1250 to Queen's Hospital, Birmingham, for the endowment of a "Leonard Dingley" bed.

Dr. Gustave Monod, M.D. Paris, M.R.C.P. Lond. (of Vichy), has been commissioned by the French Ministre de l'Instruction Publique to report on the organisation of post-graduate study in Great Britain and in the United States, and has arrived in London with that object.

A Medical Magistrate.—Mr. John Wallis Gill, of St. Germans, has been placed on the commission of the peace for the county of Cornwall.

Royal Institute of Public Health.—A course of instruction in the Diagnosis and Treatment of Tuberculosis, for tuberculosis officers, school medical officers, and other medical practitioners, will begin on Friday, Jan. 16th. Lectures will be given by Dr. C. Addison, M.P., Dr. F. E. Fremantle, Dr. A. C. Inman, Mr. J. J. Perkins, Dr. T. N. Kelynack, Mr. Henry J. Gauvain, Dr. Cecil Wall, Dr. Clive Riviere, Dr. David J. Williamson, Dr. F. J. Wethered, and Dr. H. Owen West. Bacteriological demonstrations will be given in the laboratories of the Institute, and visits will be arranged to the tuberculosis dispensaries and sanatoriums. The lectures will be delivered at the Institute on Fridays at 5 p.m. All interested are invited to attend the first lecture on Friday, Jan. 16th, by Dr. Addison. An optional examination will be held at the close of the course, and certificates will be awarded to successful candidates. The fee for the course is 3 guineas. Further information may be obtained from the secretary, 37, Russell-square, London, W.C.

Hall.—On Jan. 3rd, at Bankside, Mayfield, Sussex, very suddenly, Henry John Hall, M.R.C.S. Eng., L.R.C.P. Lond.

Hewlett.—On Jan. 7th, at 12, Colnette-road, Putney, S.W., after a long illness, Louise, the wife of R. Tanner Hewlett, M.D., F.R.C.P.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answer to Correspondents.

MEDICINE AND MISSIONS.

In the current number of *The East and the West* there is series of articles on missions in their various phases al over the world. The whole review is interesting, and th tone generally so liberal and tolerant that even the ur friendly critic of missions would find little to cavil a Mr. Henry Rundle writes on Medicine and Missions, an gives a comprehensive review of the work of Britis medical missions from the year 1703, when Genera Codrington left a portion of his West Indian estates t the Society for the Propagation of the Gospel, making pro vision that "a convenient number of professors an scholars be maintained there to study and practise physi and chirurgery as well as divinity." That was the beginning of a great and beneficent enterprise, and to-day th principle of this wise bequest has so far gained acceptanc that medical work is regarded as an indispensable part o the regular business of every missionary society. Th story of this development is told outline, and space is found for a of the work of many pioneers missionary effort. Especially noteworthy are the referenc to the really wonderful achievements of Dr. A. M. Pennel of Bannu, and Dr. Wilfred T. Grenfell, the devoted an heroic friend of the people of Labrador. Although th writer's whole-hearted sympathy with Christian missio is never concealed, he treats his subject frankly from th point of view of the doctor, and therein, to our thinking lie the chief value and interest of this contribution. T urge the importance of medical science as an adjunct missionary enterprise is perhaps superfluous at a tim when every missionary society is eagerly anxious develop that side of its work, but Mr. Rundle does mo than this when he shows that medical science has foun and may still find, its highest opportunities of scien in coöperation with the evangelistic efforts of Christia missions. Thus, perhaps unconsciously, the appeal of th paper is to the medical quite as much as to the missiona student.

KIKUYU.

This name, scarcely known to many a short while ago, has now sprung into striking prominence amongst Anglica Churchmen, Nonconformists, Roman Catholics, and others The name is said to be derived from Kuyu, a fig. Fig tree are very abundant in the country. The Akikuyu are the result of an inter-mixture of the Masai and the Bant Their numbers are estimated at a million. Kikuyu is the twenty-third Uganda railway station, 342 miles from the coast, at an altitude of 6700 feet. The country is a fertile wooded strip extending from the hog-backed mountain called Ngongo Bayas northwards to Kenia. The people are intelligent and industrious, and cultivate their plantations with great care. They are essentially agriculturists and cultivators, and lead a semi-settled life—that is to say, they burn a clearing in the forest, build a village, and cultivate for a few years. As soon as the soil shows any sign of exhaustion they move on, burn another clearing, and repeat the same process. They make good workmen under European or Indian surveillance, and do the greater part of the manual labour in the workshops of the Uganda railway. It was in 1849 that Dr. Ludwig Krapf, a missionary, who had been expelled from Abyssinia, discovered Mount Kenia. He worked with the Rev. John Rebmann, who also made discoveries. Further particulars will be found in "Drumkey's Year Book for East Africa." The name of a medicine man there is Mun-du-Mu-gu, which, according to Mr. A. W. McGregor, of the Church Missionary Society, means a "clever man." We discussed this matter and these interesting people in a long review in The Lancet of June 11th, 1910, p. 1621, of a book entitled "With a Prehistoric People: the Akikúyu of British East Africa," and our readers may wish to turn again to that volume in view of the topical importance of Kikuyu, which seems to have become a pivot of the world.

BABY No. 30.

Herr of Briesen, Western Prussia, and pon as pillars of the State tha d the holy state of matrimony. Their thirtieth child has just been born, and they have been honoured by the publication of their portraits in the *Daily Express*. We hope that all the 29 other children ar alive, for the family which produces the greatest numbe of babies comes second to the family which succeeds rearing the greatest number properly.

CONSUMPTIVES AND THE POST OFFICE.

WE have received a letter from Toronto, dated Dec. 17th, [illegible] bears a red two cent postage [illegible] head obliterated by the usual [illegible] tached thereto is a black frame [illegible] account of the Muskoka Sanatoriums for Tuberculosis.

THE CARE OF THE BABY AND THE SICK.

WE have had occasion previously to refer to some of the useful domestic series of pamphlets issued at the price of 1d each (or post free for 1½d.) by the Women's Industrial Council, 7, John street, Adelphi, W.C Two new ones are *How to Take Care of Baby*, by Selina F. Fox, M.D., B S., and *How to Take Care of the Sick at Home*, by W and S. Rintoul. Of the first we can cordially endorse the words of Dr. Eric Pritchard, who writes the preface, that its pages seem to contain exactly the right amount of information, neither too much nor too little Of the second, it may be said also that it gives just that kind of information that every householder ought to possess in regard to accidents and the care of the sick; for, as Sir Victor Horsley, who contributes a preface, says, "the personal combat cannot be warded off even by the possession of means to pay for skilled aid."——Mrs. Frank Stephens's penny booklet for mothers is in its 321st thousand. It is called *How to Rear a Baby*, and is published by Messrs. Horace Marshall and Son, London. It is full of good common sense, and at the same time also sound teaching, even if a little extreme in some points. The danger of abrading the delicate protective epithelium of the infant's mouth by the indiscriminate practice of so-called "mouth cleansing" has been several times referred to in our columns, and we certainly cannot approve of its recommendation in general terms (p. 27) without a single cautionary word.

A NURSING JOURNAL FOR SOUTH AFRICA.

THE first number [illegible] October, seems [illegible] task to which it [illegible] of the nursing [illegible] it in the bonds [illegible] it to a realisatic [illegible] tains varied material of interest to nurses, including articles on Operating Theatre Methods and their Evolution, by Mr. D'Arcy Power, F.R.C.S., and on Infant Feeding, by Dr. J. Bruce Bays, with nursing news, both local and general. It is to be published monthly at East London, price 10*s*. 6*d*. per annum, or 1*s*. a copy.

THE PARIS, LYONS, AND MEDITERRANEAN RAILWAY.

[illegible] Company have [illegible] atlas of their [illegible] and contain [illegible] h the system [illegible] in the Riviera, and in Savoy and Dauphiny. The atter section has coloured pl[illegible] f Napoleon crossing the Alps [illegible] luring the manœuvres of 1913 [illegible] oloured plates representing the battle of flowers in the Bay of Villefranche and the carnival at Nice Both ections can be obtained free from the offices of the ompany, 179, Piccadilly, London, W.

USEFUL diary, bound in red cloth and giving a clear page f 8 by 5 inches to a day, together with an alphabetical ndex at the end, will be sent free of cost to our readers n application to "Lactéol du Dr. Boucard," 9, Gamage Buildings, Holborn, London, E.C.

RATUM.—The Notes from Canada in THE LANCET of Nov. 29th, 1913, contained a mistake. Our correspondent stated that Dr John Stewart had recently been appointed professor of surgery in the Halifax Medical College It has been pointed out to us that the Halifax Medical College has been taken over by the University of Dalhousie, and he professor in surgery is Dr E. V. Hogan

MMUNICATIONS not noticed in our present issue will eceive attention in our next

A DIARY OF CONGRESSES.

e following Congresses, Conferences, and Exhibitions are announced n 1914 —

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1913 were given THE LANCET of Dec. 27th, 1913.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1913 will be dy shortly. Bound in cloth, gilt lettered, price 16*s.*, rriage extra.

Cases for binding the half-year's numbers are now ready. oth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions ich are sent direct to the Proprietors of THE LANCET at ir Offices, 423, Strand, London, W.C., are dealt with by m? Subscriptions paid to London or to local newsagents th none of whom have the Proprietors any connexion whatr) do not reach THE LANCET Offices, and consequently uiries concerning missing copies, &c., should be sent to Agent to whom the subscription is paid, and *not* to E LANCET Offices.

Subscribers, by sending their subscriptions direct to E LANCET Offices, will ensure regularity in the despatch their Journals and an earlier delivery than the majority of ents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin per) is published in time to catch the weekly Friday mails all parts of the world.

The rates of subscriptions, post free from THE LANCET ices, have been reduced, and are now as follows :—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
ne Year	£1 1 0	One Year	£1 5 0
ix Months	0 12 6	Six Months	0 14 0
hree Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to dical Subordinates in India whose rates of pay, including owances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

would afford a fact of value in estimating his prospects of life. It may be added that it often supplies a determining factor in judging of the necessity of antityphoid inoculation under particular circumstances.

VARIETIES OF POLICIES.

The last 30 years have seen the introduction of much variety in the form of assurance policies. Endowment assurance, the limited premiums policy, and the convertible term policy have all found their vogue; as has the double endowment form, sometimes granted without medical examination. These are, it is true, matters for the actuaries, but the head office physician needs to understand their bearing, that he may help his actuarial colleague. We have come gradually to learn the principles upon which the acceptance of second-class lives should be based. Extra risks may be divided broadly into three classes: those in which the risk is of an increasing character—for example, heart or kidney disease; those which are diminishing risks, especially tubercle; and lastly, those which apply continuously throughout the expectation period, such as occupation or climate. The form of rating to be chosen may depend upon the kind of extra risk, and it is often possible to select a description of policy which meets the risk involved, with the maximum of safety to the office and of convenience to the insurer.[10]

TUBERCULOSIS.

Two topics of surpassing interest confront us in looking forward. Tuberculosis and cancer together account for about 15 per cent. of the deaths of insured persons; and a more important fact is that many of these deaths occur in early adult or middle life. What people die from in old age has for us as insurance physicians little more than an academic interest, but the causes of premature death, these it is our business to study closely. How are these diseases going to affect our work in the future? For we ought to look forward. What we are doing to-day is to advise our offices how to estimate the risks, not so much of the present as of the future, and it is the results of the future which will justify our advice. Now, as to tuberculosis, we know that a great change has occurred; that the discovery of its living germ has given an immense impetus to the movement, which was already begun, for treating the disease on hygienic lines. Sanitation, notification, and sanatorium treatment, to which we may now add special dispensaries, health visiting, and probably the use of tuberculin, have acted (or will act) both by way of prevention and by way of cure. And the results are seen in the returns of deaths, for the mortality from phthisis has not only declined rapidly but at an accelerated rate. For adults over 25 years of age the death-rate is now about 40 per cent. lower than it was 30 years ago, and the fall has been greater in the case of women than in men.[11] If the present rate of decline continues for another 30 years, and there is a good prospect that it will do so, the old plague of consumption will wear a very different aspect in all civilised countries. This is a remarkable prospect. For insurance purposes it must be discounted a little, because the returns are for the whole community, and the insured classes have already been in the enjoyment of some of the advantages which are now extended to those who are poorer; it follows that they may not share to the full extent in the reduction of mortality. Yet evidence enough is left greatly to modify our outlook. In view, then, of the present lightening of the risk of phthisis and the prospect of its further reduction, we are surely justified in treating those proposers who show a liability to tubercle with less rigor than in the past. Researches which have been made during recent years into the family history of the disease, amongst which those of Dr. T. Glover Lyon and Mr. Manly[12] may be mentioned, have tended to discount its influence in increasing the risk, yet there are offices which still make a rule of imposing an extra rating upon all proposers who have lost a parent from phthisis. We may now, I think, regard a family history of tubercle as of little importance if the subject himself has good lungs and sound habits; we may accept many cases at tabular rates where the suspicion of liability rests on slight evidence; and we may be content with lower ratings where these are called for.

CANCER.

I pass on to speak of cancer. The past 30 years has seen the recorded mortality of this disease in England and Wales to rise in the case of males by 150 per cent., and in that of females by 60 per cent.,[13] and this despite the great advances in surgery, in sanitation, and in medical knowledge which have reduced the fatality of other diseases. Cancer now accounts for 1 in every 9 deaths among all adults of 25 years and upwards. In women between the ages of 40 and 60 years it accounts for 1 in every 5 deaths. He must be a bold man who would challenge the plain significance of these records, and still seek to explain away the apparent increase of cancer, large and continuous as it is, by the hypothesis of better diagnosis and certification. Just as we can look on tuberculosis as a diminishing cause of death in insured life so we must regard cancer as an increasing cause. We ought then, it seems to me, to scrutinise our methods of dealing with this risk, and especially to re-study the bearing of family history. The late Dr. J. F. Payne brought before this association in 1897[14] the results of his own studies, in a paper which was a model of dispassionate and balanced statement. His conclusions for the estimation of lives with a family history of cancer were pretty severe, and did not find full acceptance at the time, nor did Dr. W. S. Lazarus-Barlow and Dr. Gordon Taylor in their paper in 1905[15] take a like view. The subject needs further consideration now. As regards the insurance of women, the liability to malignant disease of the uterus and breast during the middle period of life has become so great that it is a question whether female lives in whose family histories there is a single such record amongst parents, brothers, or sisters should ever be taken without a rating. The increase of cancer dictates also special care in dealing with evidence of slight derangement of various organs, and especially of the digestive system, for it is in this tract that the increase of mortality has been most marked. This may be illustrated by an instance which came under my notice. A man, aged a little over 60, was examined, I was told, by one of our best physicians; he was tall and thin and had some dyspeptic symptoms, but was taken as a first class life for a large sum, spread over many offices He died within a year of cancer of the stomach

Prospect of Lower Mortality

It would be interesting to pursue further our outlook into the future Besides tubercle and cancer there are other diseases which are changing Diabetes, for instance, is an increasing cause of death But when we regard, on the one hand, the steady advance in medical and hygienic knowledge, and on the other the fact of a lowered general death rate, we have warrant for looking forward to a lessened mortality among assured lives The companies naturally base their rates upon past experience, hence the improved results which we foresee will come to augment their bonuses, but in the meantime they may, perhaps, consider themselves justified in doing something to ease the rates of premium from time to time The O^m basis will need to give way to a new one as the office records of a realised lower mortality accumulate

Conclusion The Science of Prognosis

Time does not permit a full reference to accident insurance, which forms an important part of the scope of the association, and upon which valuable papers by Sir R J Collie, Sir T Oliver, Dr G G Howitt, Dr F Parkes Weber, and Mr D Knocker *will be found in the Transactions for 1908–09 and* 1910–11

The department of medicine which this association represents is not only one of practical utility in its aim, applying the medical art to the practice of life assurance, and thus safeguarding the welfare of men or of those dependent on them, but it has also a scientific value, and contributes to the whole purpose of medicine itself For it cultivates in the physician the art of prognosis, the habit of forecast—may I say the prophetic instinct? It casts a light upon symptoms and signs by which we may interpret them, not for the present but for the future It leads to the study of tendencies to disease as well as of disease itself, it should help us to understand types of constitution, temperaments, diatheses, and idiosyncrasies Which of us is not thankful for the experience it brings in the examination of the healthy as well as the sick? There is something, again, in the uncertainty of the results of all insurance operations that gives scope for the play of the imagination, and appeals, shall I say, to the sporting instincts that lie, whether hidden or obvious, in all human nature? But it is as honest work, good for the community, and grounded on scientific medicine, that the patient labours of the life assurance examiner may be commended They are given, no less than the other activities of our profession, to circumvent disease and death and to promote reason and order in the affairs of men

THE VALUE OF THE CARDIAC SIGN IN CANCER[1]

FIFTY CONSECUTIVE DIAGNOSES WITH 6 PER CENT OF ERROR

By WILLIAM GORDON, M D Cantab, F R C P Lond,
PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL

My title is of the sort that needs an apology Its intention is simply to draw attention to a method, and I do not see how the point can be clearly put otherwise For, as the proof of the pudding is, after all, in the eating of it, so the test of a diagnostic method is in the use of it Possibly there are some who may think that 6 per cent of error is excessive, for myself, I must frankly confess I could not have avoided more mistakes without help The help has been the cardiac sign to which I have repeatedly drawn attention, and the table I submit will give some idea how much I have owed to it, at the same time indicating some of the limitations of its usefulness

Since Oct 1st, 1912, I have set down in easily accessible form every diagnosis of "cancer" and "not cancer," which I have made in *cases that were definitely doubtful when they were submitted to me*, and these diagnoses I have followed up, so far as has been possible, in order to discover how many *and what kind of mistakes I have been making* The cases I present in the accompanying table are those thus recorded, and are strictly consecutive, except for two lost sight of, three in which the end was inconclusive (although all three verified the prognosis given), and a few of which it is as yet premature to speak decisively

But just as a surgeon, by selection of only promising cases, can present a surprising percentage of successful operations, so a physician, by a system of extensive hedging, may attain remarkable success in such diagnoses as he risks I would therefore point out that in the period covered by this table I do not think I have set aside more than half a *dozen cases as uncertain, preferring rather* to hazard an opinion where reasonable grounds for making one existed, and so to test fairly the measure of help which my means of investigation afforded me

The diagnoses of "cancer" which have proved to be correct divide into three groups, viz (1) a group of 5 cases in which, for reasons given in the table, the cardiac sign was not available, (2) a group of six cases of visible or tangible cancers, where its help, though real, was of minor importance, and (3) a group of 11 cases of the difficult sort in which its assistance is so extremely valuable—cases of abdominal cancer where, short of operation, direct access *to the growth is impossible.* In the whole 17 cases in which the cardiac sign was available it was only absent in one

The diagnoses of "not cancer" are 25 in number. The verifications will, I think, be admitted to be sufficient In all but two of these the cardiac sign could be used, and is seen to have been present only once

Needless to remark, the sign was never the sole ground of an opinion, I would only emphasise its great usefulness as a help

To the details in the table I shall only add such brief notes as are necessary of the cases where a diagnosis of cancer has proved to be correct, and a

rather more detailed account of my mistakes, leaving wholly to the table, as sufficient, my references to the "non-cancerous" cases.

The first case of error seems to me to have presented almost insuperable difficulties; the post-mortem examination was made by a very good man, or I should have doubted the findings, and I am altogether at a loss to explain the symptoms.

The second mistake, I think, ought not to have been made. The cardiac dulness was against me for what it was worth, which, however was very little, since the heart was a large one; the history pointed to gall-stones (although such might very well have been a precursor of a growth), and the duration was very short. I fancy the daughter's death from cancer and the accounts of loss of flesh may have helped to put me off the track.

With the third mistake the case is different. Here I was in numerous and excellent company in error; for the difficulties were exceptional. But I had not had the mucus microscoped nor the vomit tested, which I clearly should have had; moreover, I think, the intractability of the disease and the sense of resistance over the pylorus and cardia should have outweighed the comparative youth of the patient, his non-cancerous appearance, and the absence of the cardiac sign.

To save space I shall allude to the recumbent cardiac dulness as the R.C.D. It goes without saying that the cases in which it has been recorded have no such invalidating accompaniments as I have explained elsewhere; where such were present (and the dulness is consequently not recorded) a note of them in brackets is added in the table. It has seemed best to omit all names in connexion with the cases.

THE CASES.

(a) *The Mistakes.*

CASE 1.—The patient, a married woman aged 59, had suffered for four months from dysphagia, with severe pain in the throat soon after swallowing, at the level of the top of the manubrium, and over the second dorsal vertebra. When solids were stopped the pain lessened, and got bad again when they were resumed. The thyroid seemed somewhat fixed, and was sometimes enlarged; occasionally she lost her voice, and now and then her breathing was whistling. There were small glands over the left clavicle. She hawked up strings of ropy mucus but no blood. The breath was offensive and the tongue coated. In the four months of illness she had lost a stone and a half. The abdominal skin was rather inelastic. The R.C.D. was 1$\frac{5}{8}$ inches wide. For two years she had been an invalid, with a high-tension pulse and retinal hæmorrhages. The urine was 1005, with a good trace of albumin; no sugar. Her sister had died from cancer. Post mortem no growth was discovered, nor, in fact, anything to account for the dysphagia.

CASE 2.—The patient, a married woman aged 72, was seen on July 13th, 1913. She had jaundice and a distended gall-bladder, which felt almost as large as a cricket-ball. The jaundice, which was considerable and increasing, had come on a few days previously with a good deal of abdominal pain, which persisted, chiefly in the right side. The tumour was clearly gall-bladder as the kidney could be felt behind it. There was slight shifting dulness in the flank. The abdominal skin was thin and rather inelastic. A tender swelling was palpable in the region of the pancreas. She had been losing a great deal of weight lately. Her daughter had died from cancer at the age of 40. Twenty years before she had had severe abdominal pain, but never jaundice, and the abdominal pain had often recurred since for about 12 hours at a time. Her heart was much enlarged with an apical systolic murmur conducted into the axilla; R.C.D. normal; in the erect position the dulness was much increased. She suffered periodically from heart failure and dilatation. A gall-stone was passed, the jaundice and tumour disappeared, and she is now, I understand, in her usual condition.

CASE 3.—The patient, a man aged 34, had been ill with vomiting for four months. During the first month this was only occasional in the evening, copious, but unattended by either pain or hæmorrhage. A dry diet made him worse and he began to vomit all day. He was then put to bed on milk only, which was peptonised later, and he improved for a short time. Afterwards he got worse still. Horse serum by the mouth aggravated the condition; washing out the stomach gave some temporary relief. He did not look like a cancer patient. The pulse and heart sounds were feeble, but seeing that he was vomiting almost all he swallowed that was not surprising. The R.C.D. was normal. He had, of course, lost flesh, but the skin had not the dry, inelastic feeling so common in advanced gastric cancer. The feet were not swollen. There were small palpable glands in both groins, but nowhere else. There was no family history of cancer. He had always been healthy, though easily made sick. The stomach, judging by its resonance, seemed considerably enlarged, reaching to the umbilicus; there was some resistance near the usual situation of the pylorus and a feeling of thickening about what seemed to be the middle of the organ. The liver and spleen were apparently normal. The vomit, on the day I saw him, was for the first time hæmorrhagic. It was full of mucus abundantly streaked with black altered blood. Remedies were discussed to bring him, if possible, into a better state for gastro-enterostomy. But a week latter matters had gone from bad to worse; he had had hæmorrhage badly and no food could be retained; the pulse was extremely feeble. An enema of calcium chloride, adrenalin, and tinctura opii was administered every six hours to check hæmorrhage and to help him to retain the nutrient enemata which had been rejected, and in two days, a slight rally having been secured, he was operated on as a last possible chance. The operation was well borne, but cancer was discovered.

The Other Cases.

CASE 4.—The patient, a man aged 40, had had pain in the left side with cough for two months, and when seen had dyspnœa and palpitation. Blood-stained fluid was drawn off in abundance from the left pleura several times. There was no sputum. The microscoping of a small subcutaneous nodule at once gave the diagnosis of carcinoma, which a post-mortem examination reaffirmed.

CASE 5.—The patient, a man aged 53, had been ill for a month with increasing dyspnœa, but with practically no pain, and with a subnormal temperature. The whole right side of the chest was dull, swollen, and rather puffy. The heart, however, was not displaced. There was stridor over the root of the left lung, weak voice and breath sounds over the dull area on the right, and vocal fremitus lost there. The left pulse was smaller than the right. There was considerable leucocytosis, the sputum contained suspicious looking cells, and some scanty serous blood-stained fluid, obtained from puncture of the dull side, showed large grouped granular and vacuolated cells. He was evidently *in extremis*, and died in the following night.

CASE 6.—The patient, a man aged 52, seemed a rather acute and feeble case of emphysema, until spinal symptoms developed which made the diagnosis a fairly simple matter.

CASE 7.—This was a case of round-celled sarcoma in the abdomen presenting no difficulty, and the diagnosis was confirmed by operation.

CASE 8.—The patient, an unmarried woman aged 57, presented a very curious and puzzling course, beginning as a pleurisy and going on, after an interval of two months, in which she greatly regained flesh and strength, to abdominal pain and distension. She had a large fluctuating swelling in the left lower part of the abdomen, a number of subcutaneous nodules, and a hard enlarged gland over the left clavicle. She afterwards developed two patches of secondary growth in the vagina. Operation confirmed the diagnosis of cancer.

CASES 9, 10, 11, 12, 13, and 14 call for no special comment.

CASE 15.—The patient, a married woman aged 34, had a large right ovarian cyst removed on Jan. 9th, 1913, as well as a small cyst from the left ovary, that ovary, however, being left; no malignancy was then evident. I saw her in July. Since the operation there had been soreness in the left groin; she had not lost flesh, colour, or appetite; her pulse was good. A large elastic tumour occupied the left lower quadrant of the abdomen; the spleen was enlarged, descending about two finger-breadths below the ribs. The R.C.D. was only 1½ inches wide. Operation showed an inoperable cancerous mass with matted intestines. The enlargement of the spleen remained unexplained.

CASE 16.—The patient was a man aged 56. This case is of considerable interest, as his condition had been variously diagnosed. He had been suffering from abdominal pain and had attacks of constipation lasting three weeks at a time, so that a suspicion of sigmoid carcinoma had arisen. The sigmoidoscope, however, revealed nothing. Three weeks before I saw him he became feebler and had gastric pain after food, anorexia, and frequent vomiting, but no hæmatemesis. He was pale and had lost flesh. The motions presented no peculiarities. His R.C.D. was 1¼ inches wide, but in the erect position the cardiac dulness was 6 inches wide. Two very small subcutaneous nodules less than an eighth of an inch in diameter were found. I diagnosed cancer, but was uncertain of its site, and had a nodule removed and examined.

CASE 17.—The patient, a man aged 55, had been losing weight for a year, and suffered from gnawing pain, severe at times, especially after food. There was an epigastric tumour and the stomach contents showed absence of free HCl and the fæces contained occult blood. The cardiac sign was present.

CASE 18.—The patient, a man aged 53, had for five months had indigestion and occasional vomiting, but never hæmatemesis. He had anorexia, flatulence, and great weakness. The skin seemed to have darkened somewhat, and a suspicion of Addison's disease existed. A hard nodular tumour could be felt coming down from under the left ribs. His weight had fallen in the five months from 12 st. to 9 st. 4 lb. The pulse was 96, of low tension. The R.C.D. was only ⅞ in. across. I could not satisfy myself that the skin darkening was more than such as can occur in cancer cases (although it is possible secondary deposits existed in the suprarenals); he was naturally very dark. The case went rapidly downhill. No post-mortem examination was obtainable, but before death the growth had become still larger.

CASE 19.—The patient, a man aged 60, had only complained for eight weeks of indigestion and anorexia. He had lost about a stone, he thought. A slowly increasing and now large nodular, not tender, tumour, apparently in the lesser curve of the stomach and spreading over its anterior wall, was found; a hard nodule was felt in the umbilicus, and the liver was enlarged. In spite of a rather tense pulse and slight albuminuria the R.C.D. was only 1½ inches wide. No post-mortem examination was obtainable, but his medical attendant considers from subsequent observation that the case was as we diagnosed it.

CASE 20.—The patient, a man aged 57, had epigastric pain, vomiting, and occult blood in the stools. The R.C.D. was 1⅛ inches across. Death was returned as cancer of the stomach.

CASE 21.—The patient was a man aged 44. There had been very rapid wasting for three or four months and terrible pain. The vomit was slightly blood streaked. A very tender tumour in the pyloric region was found. The R.C.D. was 1⅜ inch wide. The patient died. His medical attendant had no doubt of cancer.

CASE 22.—The patient was a man aged 49. A tender tumour occupied the site of the whole stomach. He was emaciated, very pale, and feeble. There was much continuous pain, which food scarcely affected; also constant sickness which momentarily relieved the pain. The tongue was fairly clean. There was practically no cardiac dulness. At death no doubt of the diagnosis was felt by his medical man.

CASE 23.—The patient was a man aged 49. Epigastric pain had lasted four months, and had become practically constant with severe exacerbations caused by solids. His weight had fallen from 13 st. to 9 st. 8½ lb. (in a single week 5½ lb.). A tender, hard nodular tumour was palpable in the pyloric region. The abdominal skin was thin and inelastic. The R.C.D. was only ⅞ inch. The pulse and heart sounds were feeble.

CASE 24.—The patient, a man aged 62, had been losing flesh for several months, had a well-marked tumour, nodular, and rather fixed in the epigastric region, and for three or four months had had pain and anorexia, but very little sickness and no hæmatemesis. The tongue was clean. The R.C.D. was 2¼ inches wide (*so cardiac sign absent*). Both ankles had swollen. The urine was normal. Subsequent course confirmed the diagnosis.

CASE 25.—The patient, a married woman aged 55, was seen on Sept. 30th, 1913, for epigastric pain immediately after food. There was much vomiting with a great deal of mucus and great loss of flesh. The tongue was slightly furred. A tumour was felt in the situation of the spleen. There was slight leucocytosis. The R.C.D. was 1½ inches wide. The pulse was very small and weak. Her medical man writes that he thinks there can now be no doubt the case is one of cancer.

Exeter.

THE
EARLY DIAGNOSIS AND TREATMENT OF RUPTURED INTESTINE.*

BY V. ZACHARY COPE, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS, ST. MARY'S HOSPITAL, ETC.

TRAUMATIC rupture of the intestine without any wound of the abdominal wall, though not frequent, is sufficiently common to call for some definiteness as to the surest guides for early diagnosis and the best methods of treatment.

Symptoms and Diagnosis.

When the intestine is ruptured as the result of a blow on or crush of the abdomen the symptoms can be considered as due to the supervention of shock, the occurrence of peritonitis, or the presence of gas or fluid in the peritoneal cavity. Different authors have laid stress upon various groups of symptoms; but in the early diagnosis it must be remembered that the picture varies greatly, and scarcely any one symptom, with the probable exception of pain, is constantly present.

Berry and Giuseppi, in their classical article, enumerate the symptoms in the order of their relative frequency as pain, vomiting, shock, local tenderness, rigidity, distension, added dulness, rising pulse, diminished liver dulness, and occasionally melæna and emphysema. To their list might be added marked restlessness, persistent superficial respiration, and pain on deep breathing.

The symptoms of shock are frequently absent in the early stages of ruptured intestine, and are often present in abdominal contusions and injuries in which the intestine is uninjured; moreover, as most surgeons wait for the subsidence of initial shock before operating in any but the most obviously urgent cases, its presence is not of such great value in early diagnosis. Curtis has pointed out that there are occasional cases in which the shock caused by the accident passes rapidly or slowly into a collapse which lasts until death. I have seen such a case in which other injuries entirely masked the symptoms of intestinal injury. It is probable that most of such cases would terminate fatally, whether operation were undertaken or not, and it would be impossible to lay down any definite rules for guidance in their treatment.

The majority of cases have to be diagnosed by the symptoms of peritonitis, of rapid or delayed onset. The main difficulty lies when the onset is delayed or masked. The early symptoms of peritonitis may be extremely equivocal. T onset is often delayed after rupture of the intestine because the intestinal paresis caused by the injury inhibits peristalsis and allows time for the exudation of plastic lymph which seals the opening; abstention from food also aids the limitation of peristalsis. Then when local shock is recovered from or food is taken, peristalsis of the affected coil commences and serious leakage occurs.

---

* Being an abstract of a paper read before the Surgical Sect Royal Society of Medicine, on Dec. 9th, 1913.

Rigidity of the muscles of the abdominal wall is a valuable symptom if it persists for more than a few hours after the accident; the rigidity may be localised to a limited area of the parietes. The rigidity which results from simple contusion of the muscles tends to pass off within a few hours. Rigidity may also occur in cases of injuries to the solid viscera, in retroperitoneal hæmatomata, and in injuries to the lower part of the thorax. On the other hand, rigidity may be altogether absent in the presence of ruptured gut, as in a case in St. Mary's Hospital three years ago.

The pulse and temperature are not reliable guides in the early stages. In one case under my care the pulse was 80 and of good volume nearly 20 hours after the accident; in the other it kept at 70 for some 10 hours after. The temperature may be normal or subnormal at first, but tends to rise as peritonitis extends. But whilst pulse and temperature are of little help when normal, they are of considerable importance when above the normal. A gradual increase in the pulse hour by hour in the absence of signs of hæmorrhage is very suggestive; and Battle has called attention to the importance of an elevation of temperature. At the same time, to wait until the pulse or temperature rises to any onsiderable extent is like waiting until the house s well alight before trying to extinguish the ames.

Pain, when continuous and increasing in severity, s the most reliable symptom. In very few cases s it absent, and then there is usually some other efinite symptom. Pain is demonstrated in four ways. *First, the expression may be anxious and* obviously significant of pain; secondly, pain is complained of at the site of the lesion; it is coninuous, but has exacerbations. It may gradually extend or definitely shift in position. This shifting s of more value in cases of injury to the gut situated in the epigastrium; in both my patients with ruptured jejunum the maximum pain shifted rom the upper to the lower abdomen. Thirdly, pain when not complained of may be evoked by deep pressure over the site of the lesion; this deep palpation is only possible when there is little or no rigidity, but if the latter be present there is usually tenderness on light pressure. Fourthly, in many *cases the pelvic peritoneum as felt* by rectal examination is painful to pressure; this is due to the pelvic peritonitis which follows early in hypogastric injuries, later when the upper abdomen is the site of the lesion. Abdominal pain, then, followng an injury such as might conceivably cause a rupture of the intestine, and continuing for some hours with some extension of the area affected, or some definite shifting pelvicwards of the pain, is the most important symptom.

Vomiting is a frequent and important symptom, and if conjoined with pain is quite suggestive enough to justify operation. The vomiting of bilious material is said to be especially *gnificant* (Tschistosserdoff).

Distension usually signifies extensive peritonitis, and is a symptom which should not be waited for. A misleading exception to this statement *is the occurrence of what has been termed* "primary meteorism." Tschistosserdoff states that this is probably due to injury to the retroperitoneal nerve plexus. It affects chiefly the upper part of the abdomen, and as a rule comes on one or two hours after the injury. It is said that other symptoms indicating rupture are usually absent where primary meteorism occurs.

Diminution or absence of the liver dulness is a symptom which ought never to be waited for, but I do not think a hopeless prognosis should be given simply because that symptom is present. Gas escaping from the upper jejunum would soon pass in front of the liver, though frequently there is but little gas in the bowel. One of my successful cases had the liver dulness obliterated.

Edington has called special attention to the restlessness which may be one of the earliest indications of serious intestinal injury, but it is unlikely that this would be present without more definite symptoms; moreover, restlessness is often a marked feature of intraperitoneal hæmorrhage.

Superficial respiration is the natural consequence of commencing peritonitis because of the pain which ensues if a deep breath be taken; it would be unlikely to be present without abdominal pain and rigidity. The signs of free fluid are not, as a rule, present in the early period, for it is exceptional for free escape of fluid bowel contents to occur at first, and the fluid due to peritonitic exudation collects later and tends to accumulate in the pelvis, where there is difficulty in demonstrating its presence.

Providing there be no lesion in the chest and that renal trauma is excluded I would submit that it would be advisable to open the abdomen on the suspicion of ruptured intestine if the following conditions be present: (1) When severe abdominal pain persists for more than about six hours after an injury, if the pain be accompanied by either (*a*) vomiting, especially bilious vomiting; or (*b*) a pulse gradually rising from the normal; or (*c*) persistent local rigidity tending to extend; or (*d*) deep local tenderness with shallow respiration; and (2) when abdominal pain is absent or only slight, but the pulse rises steadily hour by hour and the patient is very restless or listless. When marked diminution of the liver dulness occurs with any of the above symptoms, or if there be signs of free fluid in the abdomen, the indications for operation would be imperative.

Treatment.

Since the memorable case of Croft in 1889 the recognised treatment of ruptured intestine has been by operation. Various methods of closing the rent have been adopted, but it is agreed that the best plan is to suture it if possible. If the tear be too large for successful suture without narrowing the lumen of the bowel dangerously a lateral anastomosis may be done; whilst in many cases resection of the affected part is clearly required. If the duodeno-jejunal junction be the part affected a gastro-jejunostomy should be performed.

The site of the incision should be near the middle line in the epigastrium or hypogastrium, according to the position of the injury or physical signs. The injured gut is readily indicated by the gluing together of the neighbouring coils. The usual procedures for protecting the abdominal wall and the rest of the abdominal cavity should be adopted.

The main points of difference between surgeons

Is the classificatory system of relationships, after all, more logical than our own? Is there really a wide physical difference between the relationship of cousins who are offspring of a brother and sister respectively and that of cousins whose parents respectively are two brothers or two sisters? Ought marriage in the one case to be allowed or even encouraged, and in the other case as rigidly forbidden as if it were incestuous?

With a view to ascertaining whether this classification of consanguineous marriages is really important, I collected recently statistics relating to 68 marriages of first cousins, and I propose to give here a short analysis of their study. I take this opportunity to thank those gentlemen who, in response to a request published in THE LANCET and *British Medical Journal*, kindly sent me information from various parts of the United Kingdom, France, Germany, China, and Portugal. The material at my disposal comprises 61 families, of which 57 showed one consanguineous marriage each, 2 showed two such marriages each, 1 showed three and 1 four. The total number of cousin marriages thus represented was 68, of which 33 were concubitant and 35 were tabu. Following Thomson's method of showing relative fecundity and relative vitality—

33 concubitant couples had 165 children, of whom 146 survived and 11 died.

35 tabu couples had 137 children, of whom 108 survived and 29 died.

These results correspond fairly closely with those of Thomson. At first sight it would appear from both investigations that concubitant marriages are greatly superior, but when the averages are taken the difference is not anything like so marked.

Average Fecundity and Vitality.

Thomson's Cases.

133 concubitant couples averaged 3·29 children, of whom 1·74 survived and 1·54 died.

55 tabu couples averaged 3·05 children, of whom 1·30 survived and 1·74 died.

Author's Cases.

33 concubitant couples averaged 5·00 children, of whom 4·42 survived and 0·33 died.

35 tabu couples averaged 3·62 children, of whom 3·08 survived and 0·82 died.

It will be noted that the averages of the two sets of examples correspond, but that any superiority of fecundity is accentuated in my own figures. The greater vitality shown in both concubitant and tabu families in the latter examples is probably due to the fact that my figures relate entirely to civilised peoples, which presupposes greater care of offspring, whilst Thomson deals only with a savage race. Moreover, consanguineous marriages amongst civilised peoples being contracted without any reference to concubitancy or the reverse, care of offspring would not be likely to be greater in one more than the other.

As regards the influence of concubitancy as a factor of importance in the occurrence of deaf-birth, the evidence afforded by my cases is inconclusive. Of the 68 first cousin marriages, 26 showed deaf-birth, of whom 15 were concubitant and 11 tabu. Reliable evidence of deaf-birth in other generations or in collateral branches was obtainable in only two instances (both concubitant). Of the remainder, most of the deaf-births were probably sporadic; some may have been really cases of early acquired deafness from such causes as meningitis, syphilis, &c. Syphilis, too, may have accounted for a proportion of those born deaf. Except in the two examples mentioned, the hereditary nature of the deafness was, therefore, extremely doubtful. Analysis of the cases gives the following results:—

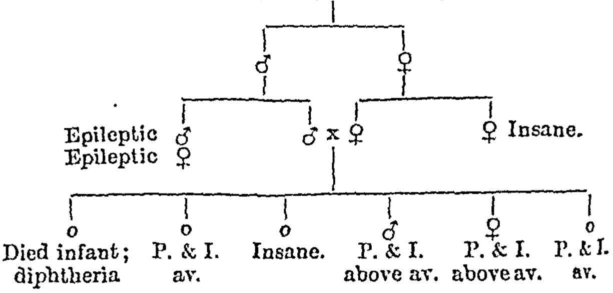
15 concubitant couples had 83 children, of whom 71 survived and 22 were deaf. Averages: 5·53 children, of whom 4·73 survived and 1·46 were deaf.

11 tabu couples had 48 children, of whom 38 survived and 15 were deaf. Averages: 4·36 children, of whom 3·45 survived and 1·36 were deaf.

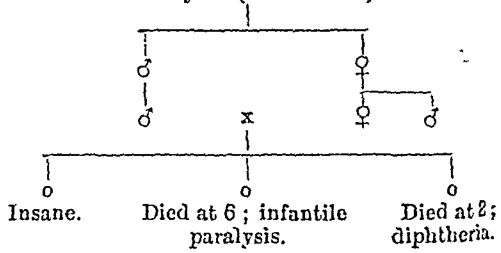
The concubitants therefore showed a greater proportion of deaf-births. The results are, however, of very little value in determining the influence of concubitancy as a factor influencing the production of deafness in consanguineous marriages. It is already well known that consanguineous marriages of the *hereditarily deaf* produce a greater proportion of deaf-births than do those in which the parents are not related.

From these results and from an examination of the family trees of my 68 first cousin marriages, I am inclined to the opinion that concubitancy or the reverse is of little influence, and that the results of such marriages is largely a question of *stock*. I have selected eight examples to illustrate this conclusion. (In these trees P. = physique; I. = intelligence; av. = average.)

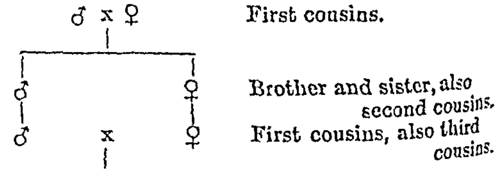
Family A. (Concubitant).



Family B. (Concubitant).



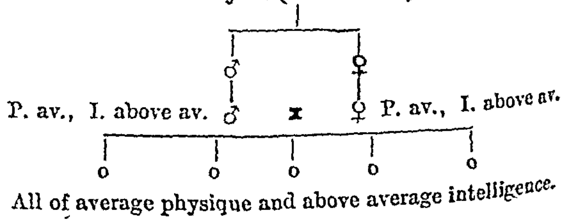
Family C. (Concubitant).



♂ x ♀ First cousins.
♂
♀
Brother and sister, also second cousins.
♂ x ♀
First cousins, also third cousins.
o
o
o

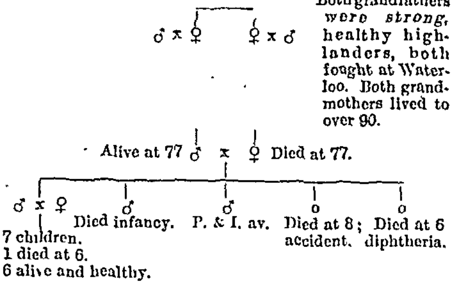
A family all of whose members are notable for physical beauty. They are tall, well-developed, normal people, without a trace amongst them of neurosis or degeneracy.

Family D. (Concubitant).



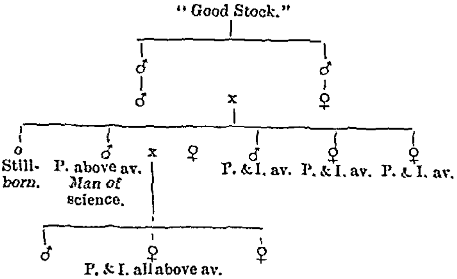
All of average physique and above average intelligence.

Family E. (Tabu).

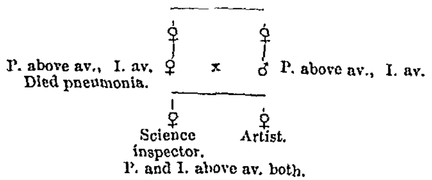


Both grandfathers were *strong*, healthy highlanders, both fought at Waterloo. Both grandmothers lived to over 90.

Family F (Tabu).

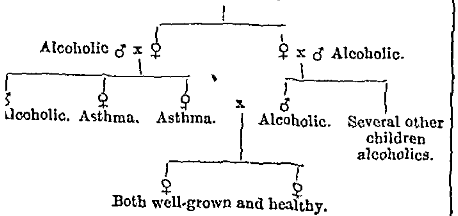


Family G. (Tabu)



♀
♀
P. above av., I. av. Died pneumonia. ♀
x
♂ P. above av., I. av.
♀ Science inspector.
♀ Artist.
P. and I. above av. both.

Family H (Tabu).



These eight examples show instances of good and bad stock in both concubitant and tabu families, and *suggest that quality of stock is all-important.* Arguing upon Mendelian lines, if the stock is good and free from taint of hereditary deafness, there is no reason why the offspring of a consanguineous marriage should show deafness, because that character (shown by Kerr Love to be recessive) is not present; whereas, if deafness should happen to be present as a family taint, the union of two blood relations, both of whom may carry—although they may themselves be hearing—the recessive character in their germ cells, would be likely to accentuate it, and recessive offspring would occur with a frequency which would follow the Mendelian hypothesis. That is to say, they would act as "impure dominants," *giving rise to three dominants to one recessive*, of which the recessives would breed true and of the three dominants two would be impure.

Queen Anne-street, W.

RECURRENT INTUSSUSCEPTION:

THE RECORD OF A CASE WHICH WAS OPERATED UPON THREE TIMES.

BY G. GREY TURNER, M.S. DURH., F.R.C.S. ENG.,
ASSISTANT SURGEON, ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE; LECTURER ON SURGERY IN THE UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

I HAVE been prompted to record the following cases as the result of reading an annotation on the subject in THE LANCET of Dec. 20th, 1913.

The patient (Reg. No. 1040) first came under my care at the Royal Infirmary on June 13th, 1907, being at that time 8 months old. On the day preceding admission the baby vomited and was rather restless during the night. About 4 A.M. he awakened suddenly, and the mother thought he looked very pale and ill. The bowels were moved, and blood was noticed on the napkin. From this time the child kept tossing about and crying. At 11 A.M. a medical man saw the patient and, finding an intussusception per rectum, sent the child straight into hospital, where I operated at 1 P.M. The invagination extended from the ileo-cæcal valve to the rectum; the appendix was not involved, so that it was of the ileo-colic variety. Reduction was effected by manipulation, but to complete the process it was necessary to bring the involved bowel outside the abdomen. The lower end of the ileum was found to be much thickened, and there was a very definite indentation at one point, while the glands in the mesentery were enlarged. The child made an uninterrupted recovery, and in July was seen and found to be perfectly well in every way.

On Oct. 8th of the same year the child was again admitted with a recurrence of the intussusception. He had been very well until the day of admission at 3 P.M., when he had an attack of abdominal pain and passed blood per rectum. When seen the patient was found to be in good condition, but was evidently uneasy in the abdomen, and a mass could be felt in the epigastrium, but there was nothing per rectum. At 9 P.M. I opened the abdomen through the old incision. The intussusception was of the same variety as before, the ileum entering the large bowel as far as the middle of the transverse colon. This time reduction was very easy. The lower two inches of the ileum were very much congested and thickened, and felt almost as though there might be a polypoid growth inside. The bowel was opened at this point, and a small portion removed for microscopic examination; there was no polypus, but the wall was much thickened. At the same time an enlarged gland was removed from the mesentery. Under the microscope both gland and bowel only showed evidences of inflammatory œdema and congestion, but neither was stained for the tubercle bacillus. In the hope of preventing a recurrence of the invagination the lower four inches of the ileum was stitched closely to the cæcum in front of the mesentery, interrupted suture of fine chromicised catgut being used. The abdomen was closed

tion, this patient was again admitted with a recurrence of his previous symptoms. Since the last operation he had kept very well until noon of the day before admission, when the mother noticed that the child held the abdomen as if in pain, but did not vomit. The bowels were moved naturally, and he passed a good night. All went well until about two hours before admission, when he passed blood and vomited, and from that time there had been continuous straining and further vomiting. When admitted the patient was found to be a big, fat, strong-looking boy in good condition. A mass typical of intussusception was felt in the abdomen, but nothing per rectum. For the third time the abdomen was *opened* by an incision through the old scar. The intussusception extended from the ileo-cæcal valve to the middle of the transverse colon, and was easily reduced. The suture of the ileum to the cæcum had not held firmly, though there were long flimsy adhesions between the two. There were two or three undoubted tuberculous ulcers in the ileum, with tubercles on the peritoneum over their site; and one of these, that nearest to the ileo-cæcal valve where the bowel had been previously incised, had formed the apex of the intussusception, as it was very much indented in the centre and much thickened. There was also a large mass of tuberculous glands in the mesentery of the lower ileum. In order to short-circuit the affected intestine, and also to provide against recurrence if possible, a lateral anastomosis by direct suture was made between the ileum above the ulcers—i.e., 18 inches from the cæcum—and the transverse colon. The abdomen was again closed with through-and-through silkworm gut, and recovery was without incident.

In the light of the above findings the gland and piece of bowel removed at the second operation were re-examined, but there were no appearances that might fairly be interpreted as being due to tubercle.

In June of 1913 the mother brought the patient to the hospital at my request. He was then a well-nourished, healthy boy between 6 and 7, and had never had a bad symptom since the last operation. The bowels acted regularly, and the abdominal scar was very strong.

The case is a good example of a recurring intussusception, which is a rare condition, though I see no reason why it should be so. For me the especial interest is in connexion with the causation of intussusception. Most operators have noted the thickened, indented area in the last few inches of the ileum. I have often thought that this area probably represented an early tuberculous invasion of the bowel wall, and in several cases I have also observed the presence of tuberculous glands in the mesentery. In the case under discussion the condition at the second operation strongly suggested tubercle, and the findings at the third operation left no doubt as to the tuberculous factor in this particular case.

If an early intestinal tuberculosis is commonly the cause of intussusception it may also explain the infrequence of recurrence, because of the well-known influence of laparotomy on abdominal tubercle. Why the disease should have steadily progressed in this case I do not know.

In another case there was evidently a recurrent intussusception which underwent "spontaneous reduction," a rare event of which I have previously recorded an example.[1]

The patient (Reg. No. 2872), aged 7 months, was admitted to the infirmary on April 20th, 1910. There had been a sudden attack of screaming and kicking at 10 A.M., and at 2 P.M. vomiting commenced and had been continuous since. Castor oil was given at 3 P.M., and at 4 P.M. blood and mucus were passed per anum. On admission at 8 P.M. the child looked in good condition, but was having an attack of pain. A sausage-shaped tumour, which hardened and relaxed, could easily be felt in the left iliac region. I operated at once, the abdomen being opened by a median incision below the umbilicus. The intussusception extended from the ileo-cæcal valve to the rectum; it was of the ileo-cæcal and ileo-colic variety. The indentation of its commencement was in the anterior surface of the cæcum, and not in the ileum. The invagination was easily reduced. The abdominal wall was closed with through-and-through silkworm gut sutures, and the patient made a good recovery.

This child was readmitted on July 28th, 1911, apparently with a recurrence of the intussusception. He had been seen by Dr. E. D. Smith, of Swalwell, one of our old house surgeons, who sent him into hospital with the following note: "This child has had diarrhœa for the last two days. To-day he was playing in a field, but came home at 2 o'clock vomiting, and when he was taken up his legs were covered with blood. I saw him at 2.45, and on examination the entering layer of bowel is found protruding from the anus. I was easily able to pass my finger up the anus between the outer layer and the entering layer of bowel. On examining the abdomen I can feel no lump, probably owing to the child resisting."

On admission the child looked in good condition; temperature 98° F., pulse 118; he had not vomited for two hours. There was then no bowel protruding from the anus, and no definite tumour to be felt abdominally, but per rectum a cone of bowel could be felt, the finger passing into its summit as though it were the apex of an intussusception. In the light of the history and the finding of the rectal examination I felt quite sure that the intussusception had recurred and decided to operate. Within an hour of my examination I opened the abdomen through the old incision. A careful search revealed no signs of intussusception. There were some few flimsy adhesions in the region of the splenic flexure, and the bowel in this neighbourhood was reddened and œdematous, while the glands in the vicinity were enlarged. The cæcum was large and mobile, such as is found in children who suffer from intussusception. After removal of the appendix the abdomen was closed, and the child made a good recovery.

How is the recurrence of intussusception to be prevented? The first surgical principle is the removal of the cause, but this is a primary difficulty, for in children it is usually an unknown factor. If there is anything in my suggestion as to the relation of early tubercle to intussusception it does not necessitate the adoption of any special surgical measures. If for any reason recurrence is especially feared, or if it has actually occurred, what can be done? Some surgeons recommend putting a stitch through the mesentery of the appendix and fixing it to the posterior abdominal wall, while I believe others have suggested that the whole appendix should be buried in the abdominal incision. Even if successful these means could only result in fixing the cæcum, and would do nothing to prevent invagination through the valve. The measure I adopted proved futile, but might have been more successful had I used a continuous suture of silk instead of interrupted stitches of catgut; even so, abundant experience shows how difficult it is to fix two serous surfaces together, especially when one is freely movable. To be of much service I fancy it would be necessary to fix the bowel to the abdominal wall after separating the parietal peritoneum. If there is any gross pathological condition in the lower ileum not easily removable, then I should be disposed to make a lateral anastomosis as in the first case.

Taking all the circumstances into consideration I do not think it is necessary to take any special means to anticipate recurrence (except, of course, the removal of any causative factor, such as an inverted Meckel's diverticulum). In the rare cases in which the condition recurs it is always amenable to early diagnosis and operation.

Newcastle-upon-Tyne.

London (Royal Free Hospital) School of Medicine for Women: University of London.—The council have appointed Mrs. E. Flemming, M.D., B S. Lond, to the half-lectureship in medicine, and Mr. Malcolm L Hepburn, M.D. Lond., F.R.C.S. Eng., to the half-lectureship in ophthalmology. Two St. Dunstan's exhibitions of the value of £60 a year each for five years, the Isabel Thorne scholarship of the value of £30, and the Mabel Sharman-Crawford scholarship of the value of £20 a year for four years will be awarded on the results of an examination to be held in July next. A bursary for dental students of the value of £60 will also be awarded for the course beginning October, 1914. Further particulars can be obtained on application to the secretary, 8, Hunter-street, Brunswick-square, W.C.

[1] A Note on Intussusception in Children, Northumberland and Durham Medical Journal, February, 1903.

NOTES ON A CASE OF EXTRA-UTERINE PREGNANCY IN A RUDIMENTARY FALLOPIAN TUBE.

BY DONALD DUFF, F.R.C.S. EDIN., F.R.F.P.S. GLASG.,
DISPENSARY SURGEON, GLASGOW ROYAL INFIRMARY; SURGEON AND GYNÆCOLOGIST, GLASGOW CENTRAL DISPENSARY; ASSISTANT GYNÆCOLOGICAL SURGEON, GLASGOW MATERNITY AND WOMEN'S HOSPITAL, ETC.

CASES of extra-uterine pregnancy are sufficiently common, so that one would expect the cause of the condition to be understood at this time of day when so much pathological work has been undertaken in connexion with the female pelvic organs. We are, however, no nearer the actual reason why pregnancy should take place ectopically in a large number of cases. Why a woman should bear children normally for a pregnancy or two and the following pregnancy should be abnormal in its site is a problem yet to be solved in these cases where there is no detectable occlusion of the uterine end of the tube or demonstrable lesion in the tube itself.

As a general surgeon, and not in the practice of obstetrics, I cannot claim to be able to throw any light on the causation of ectopic pregnancy, but the case I now report is of much interest to surgeons and obstetricians alike, not only on account of its rarity, but as showing that fatal hæmorrhage may result from a small, apparently unimportant source of bleeding within the abdominal cavity. The history and details of the case are as follows.

The patient was admitted to the surgical wards in the Glasgow Royal Infirmary on May 27th, 1910, complaining of severe pain over the lower part of the abdomen; the pain had been present only a few hours, was severe in character, and accompanied by sickness, but she had not vomited. She was somewhat collapsed, restless, and had marked pallor. She had passed her normal menstrual period by three days only. The temperature was 97°F. and the pulse 110; the abdomen was considerably distended, and tenderness was present in the lower zone. Rigidity was not a marked feature. Bimanual examination revealed a boggy mass in the left fornix.

She was taken to the operating theatre immediately and the abdomen was opened in the middle line. A considerable quantity of free blood was present within the abdominal cavity. The right appendages were found to be absent; no trace of ovary or tube could be found. On the left side a mass, rounded and fluctuant, was felt, and this at first was thought to be the gestation sac of an extra-uterine pregnancy. The tube and infundibulo-pelvic ligament were rapidly clamped, and on further investigation the mass proved to be blood-clot with some fluid blood in its centre. The right side of the pelvis was again explored, but all that could be detected as representing the annexa on that side was a small, red, thickened spot over the right cornu of the uterus. I thought the case was one of left tubal abortion, and I rapidly removed the clamped tube together with the ovary, cleared out the remaining clot, and closed the abdomen in layers, the whole operation being completed in 15 or 20 minutes.

The removed left annexa were subsequently examined, but I could detect nothing abnormal, and the case remained for the time a puzzle. The patient was placed in the Fowler position and treated with salines, but she did not survive beyond 50 hours after the operation.

A post-mortem examination was made by Professor J. H. Teacher, and a specimen has been prepared by him showing the abnormal uterus. He has also prepared sections from the rudimentary tube. His specimen shows features of considerable interest. On the right side there is absence of the mesosalpinx, and the right tube is represented by a small thickening at the uterine cornu. The post-mortem report states that the uterus is distinctly enlarged and has a thick decidual endometrium, but no ovum is visible. The left appendages, which had been removed, showed a small tortuous tube. The ovary is large and smooth with some blood on its surface; the enlargement is due to a corpus luteum cyst situated at the uterine end and a recent corpus luteum at its outer pole. No pregnancy can be detected on this side. The right ovary could not be found, and the right tube was represented by a thick fusiform stump set on the top of the right cornu rather than in the normal line of the tube, and the upper surface of this shows an area of blood clot a quarter of an inch in diameter. This body appears to be a tubal ovum. Microscopic sections of the thickening at the right cornu show this to be a small deformed tube containing fragments of an early ovum—villi, plasmodial masses, and the characteristic wall of an early implantation cavity.

There are several points of interest in this case. That the condition is rare will readily be admitted. I have not been able to find reference to an exactly similar case in a search through a considerable portion of the literature on ectopic pregnancy. The cases recorded of this malformation of the tube are few. There have been noted cases of supernumerary tubes. Accessory ostia have been seen in about 3 to 5 per cent. of cases. Accessory fimbria have been seen; abnormalities in length have been noted, especially in connexion with ovarian hernia. Absence of the tube when it occurs is most frequently unilateral and associated with uterus unicornis. A case has been recorded in which the uterus and vagina were well developed as in the present case, but the right tube and ovary were absent. When the ovary is absent there is usually tubal defect as well, but this is not invariably the case. Williams and Ballantyne have noted a case where there was absence of the outer two-thirds of the tube, and Marchand a case where in addition the ovary was absent. The cause of these abnormalities of the tube has been asserted to be fœtal peritonitis. In my case the uterus is well developed, but the whole of the right tube—except a very small stump—and the right ovary are absent. The deformity is of sufficient note to warrant the publication of the case, and the interest is considerably added to when gestation has occurred in the rudimentary tube. Obviously this is a case where the ovum has migrated from the left side, and there remains the additional proof, the presence of a recent corpus luteum in the left ovary. A question arises as to how the ovum gained entrance to the rudimentary tube. In the case noted by Ballantyne and Williams the outer end of the rudimentary tube had no opening, and no definite outer opening was seen in the present case, although of course it may have been closed after the impregnated ovum became imbedded. Was this a case where an ovum fertilised in the abdominal cavity attached itself to the rudimentary structure representing the tube?

A point of much importance from the point of view of treatment is the hæmorrhage which took place from the small vessels in the wall of the malformed tube. This bleeding was the cause of the fatal termination. At the operation the site of the hæmorrhage was not apparent, and certainly no free bleeding was taking place when the parts were inspected immediately before closing the abdominal cavity. Bleeding had, however, taken place afresh as shown post mortem. In a similar case the obvious treatment would be to excise the gestation area with a wedge-shaped incision and stitch the edges together.

Glasgow.

A CASE OF SCHISTOSOMIASIS JAPONICA.[1]

BY H. WHITE, M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON, R.N.

TOWARDS the end of the spring of 1913 whilst serving in H.M.S. *Cadmus* in the Yangtse River, I had on board a case of this disease, which is of somewhat rare occurrence among white people, although quite common among the Chinese and Japanese. The patient belonged to the ship, and the following is the history of the case.

On June 10th the patient came to me complaining of pains in the lumbar and epigastric regions and that he had not been feeling well for some days previously and had eaten nothing for two days. On examination he had a temperature of 103·4° F. and a pulse-rate of 90. No physical signs in the chest were observed, but there was very slight tenderness in the epigastric region. The spleen was not palpable; a blood film examined for malaria was negative and Widal's serum reaction was also negative. A differential white cell count showed an extraordinary increase of eosinophiles amounting to 56 per cent. The patient was kept in bed on low diet, the morning temperature being 99·4°. Two days later a small patch of urticaria appeared in the hypogastric region to the right of the mid-line; the next day it had faded, and a similar patch came out to the left of the mid-line. Stools were examined for ova, and one of ascaris was found; this, however, would hardly account for the great eosinophilia present. Schistosomiasis was suspected, so the patient was sent to the Catholic Mission Hospital at Hankow, where we happened to be stationed. Here he was placed under the care of Dr. R. Aird, to whom I turned him over. By the courtesy of Dr. Aird I was enabled to follow the case. Santonin (gr. 5) was given, and one ascaris was passed. The stools were examined daily for the schistosomum ova; after four days they were present, which was one week after the onset of the symptoms. The temperature continued of the septic type, ranging from normal or subnormal in the morning to upwards of 102° in the evening.

The treatment tried was varied, as so little is known of this disease. Anthelmintics were given, such as santonin and felix mas, all to no purpose. Injections of quinine hydrochloride and a course of arsenic were also tried. No drug seems to affect the course of the disease. The patient steadily lost weight and became somewhat emaciated. The fever subsided very gradually, taking over six weeks to reach normal. A blood count done weekly showed eosinophilia varying from 50 to 70 per cent. After six weeks at Hanknow he was sent to the naval sick quarters at Wei-hei-Wei to convalesce, and returned to the ship a month later, looking very thin and ill, the eosinophilia being 47 per cent. After rejoining he suffered from pains in the legs when standing for a short time, and noticed that his hair was falling out. As he was somewhat anæmic (red cells 4,800,000) I prescribed some iron and arsenic. A big improvement in his general health followed, and his hair ceased to fall. As we were then at Hong-Kong refitting I sent him up to the Naval Hospital to have his stools examined to see if they were free from ova; the examination revealed the presence of ova of ascaris and trichocephalus dispar. Extract of male fern was given, but no worms were passed. Further frequent examinations of the stools proved them to be free from ova, so the patient was returned to the ship.

This infection is only found in the Yangtse Valley above Kiukiang, sufferers from it being those who have had some connexion with the waters from the paddy fields, such as people who earn a livelihood by working in these fields or those who walk about in them whilst shooting snipe or duck. These paddy fields are covered with water to a depth of from two to six inches. My patient told me that he often killed his wounded birds by biting the backs of their heads. This was probably the channel of infection in his case, although Dr. J. A. Thomson, of Hankow, who has seen a good number of cases, prefers the theory that the infection enters the body through the skin or *viâ* the rectum.

It seems to me, however, that it is very reasonable to suppose that the infection might more easily be conveyed through the mouth, as one can so easily be splashed by the water in which one is floundering about, or after picking up a bird out of the water, by brushing the hand across the mouth. Whilst we were at Hankow eight American sailors belonging to the U.S.S. *Quiros* became infected whilst bathing in the river at Yochow, their symptoms appearing two or three days later; whereas in the case I have described the patient had been shooting for the last time exactly four weeks previously. These Americans were treated by their own surgeon, Dr. Lanning, in the International Hospital at Hankow, each one receiving a different course of treatment as far as possible, the lines adopted being: Santonin, felix mas, intramuscular injection of quinine hydrochloride, arsenic by the mouth, and salvarsan intravenously, intramuscularly, and by the rectum. None of these treatments had any marked specific action on the disease, which seems to run its course unaffected by drugs.

Very little information concerning this disease can be obtained from any text-book, and for what little knowledge I possess I am indebted to Dr. Thomson and Dr. Aird, of Hankow, who are investigating it as far as possible with the little material at their disposal. Chinamen who suffer from this disease are those who are compelled to work in the fields and are continually exposed to reinfection, and among them the mortality is great, as this leads to cirrhosis of the liver, kidneys, &c., and their attendant sequelæ. The parasites themselves, which are from half an inch to one inch in length, are found post mortem in the veins of the portal system; their extra-corporeal life is unknown. It seems probable that the ova are taken in by the mouth, their walls being dissolved by the gastric juices, and the embryos which are thus set free pass through the walls of the stomach or intestine and develop in the portal veins. The ova are not found in the stools for some days after the onset of the fever. The stools at the beginning are very loose and light in colour, but after the first week or so they become formed, and the ova are found in the mucus adhering to the fæcal matter. They are easily seen with a 2/3 objective, are oval in shape, and with a 1/6 objective an embryo can be seen inside; the walls are thinner than those of ascaris. The parasites remain in the blood for some time after the symptoms have disappeared, gradually dying out as the patient recovers his strength, which returns rapidly in a temperate climate.

This disease is sometimes called urticarial fever, but the rash is not present in all cases. The most constant signs present are the prolonged fever and the large increase of eosinophiles, accompanied by the wasting of the patient. The mortality among the whites is practically *nil*, as they can so easily avoid reinfection.

ACUTE LEUKÆMIA SIMULATING CARIES OF THE SPINE.

BY H. D. ROLLESTON, M.D. CANTAB., F.R.C.P. LOND.,
SENIOR PHYSICIAN, ST. GEORGE'S HOSPITAL, LONDON;
AND
CLAUDE H. S. FRANKAU, M.B. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, ST. GEORGE'S HOSPITAL.

THE following case is perhaps worthy of publication in THE LANCET on account of its unusual clinical features.

A boy, aged 5 years, was admitted into St. George's Hospital on August 26th, 1913, with the following history. Early in the year (April) he had an attack of whooping-cough followed by measles; from these he recovered somewhat slowly, but when sent away to the country in July he appeared to be perfectly well. While away he fell from a cart, injured his back, and as a result of pain was unable to walk for a few days On his return to London, however, on August 17th the pain had gone and he was able to walk normally. On the 20th he complained of further severe pain in the back and also in the right side of the abdomen—this latter pain disappeared in two days; the pain in the back increased in severity and again prevented him from walking. There had not been any previous illness, and the family history was good.

On admission the child appeared to be well nourished, healthy, and of good colour. He was unable to stand or even sit up on account of pain in the back. On examination of the spine there was extreme tenderness over the lower dorsal and upper lumbar vertebræ, with marked rigidity of the para-vertebral muscles. No bony deformity was present; any attempt at movement caused great pain. Tenderness was also elicited in the left sacro-iliac joint on lateral compression. There was no evidence of lumbar or psoas abscess, but abdominal examination was difficult owing to distension, which was very considerable on admission. Enlarged glands could be felt in both groins, on the right side of the neck, and in the left axilla—these were mostly small, firm, and painless. There was no evidence of any spinal cord lesion; the knee-jerks were normal.

The patient was kept in bed under observation and the bowels were well opened by purgatives to overcome the distension. In spite of the rest the pain continued and the temperature became irregular; accordingly, as the case appeared to be clinically one of acute tuberculosis of the spine, a complete plaster spinal jacket was applied under general anæsthesia with the child in the hyperextended position. Prior to the application of the plaster X ray photographs were taken of the spine and pelvis on three occasions; these revealed no abnormality. After a few days the pain in the back disappeared; the temperature, however, remained irregular. The plaster was removed in five weeks, and it was then found that the pain and the rigidity of the spine had disappeared. The pain in the left sacro-iliac joint still persisted and now was also present on the right side; a double extension was, therefore, applied to the legs, with the back extended on a wedge pillow, on the assumption that the sacro-iliac joints were affected.

About four weeks after admission it was noticed that the child was becoming pale in spite of the fact that he spent a large part of the day in the open air. The pallor slowly but steadily increased, and as the face became puffy and almost œdematous lardaceous disease was suspected; the bowels, however, remained constipated and the urine was free of albumin throughout On Oct. 1st an enlargement of the liver was detected, and this steadily progressed; the organ was smooth and painless, resembling the liver in lardaceous disease, but, as stated above, confirmatory signs were absent. The spleen was not enlarged. On Oct. 24th he had a severe attack of epistaxis followed by frequent vomiting of recent and altered blood for 36 hours. On the 28th a Wassermann reaction was performed by Mr. H. W. Bayly and found to be negative. Mr. Bayly also on the same day examined the blood and reported the following condition: "Red cells, 830,000; white cells, 14,800; polymorphonuclears, 17 per cent.; lymphocytes, 81 per cent.; mononuclear cells, 0; eosinophil cells, 2 per cent.; mast cells, 0; hæmoglobin, 20 per cent.; colour index, 1·18. Considerable variation in the size of the reds; one normoblast seen." The proportion of small and large lymphocytes was not given, but from recollection the large predominated. Mr. R. R. James examined the eyes on Oct. 29th and reported: "The fundi are pale. There is a hæmorrhage below the right disc. The veins are not characteristic of leukæmic retinitis" The child gradually sank and died on Oct. 31st.

The necropsy was performed by Dr. R. S. Trevor, who has also provided us with a description of the microscopical appearances. "The ribs were thin and the cancellous spaces large and full of deep red marrow; they were so brittle that they broke almost at once on handling. The marrow of the tibia was dull red in colour and firm in consistence. The spine was very flexible and was entirely free from any evidence of tuberculosis. The cancellous tissue of the bodies of the vertebræ was so soft that it could be cut quite easily, and the compact bone was thinned out. The bone marrow was deep red in colour. The sacro-iliac joints were free from tuberculosis The skull was normal. There were three small hæmorrhages in the right retina. The liver, weight 2 lb. 4 oz., presented rounded edges and was pale, firm, and enlarged. On section it was pale brown in colour, rather translucent in appearance, but did not give the reaction for lardaceous disease. The portal lymphatic glands were not enlarged. Spleen, 2 oz., was red and engorged. Kidneys, 4 oz. each, were pale and bloodless; they looked lardaceous, but did not give any reaction. Tonsils slightly enlarged. The thymus was well developed, but was not of abnormal size. The surface of the heart was covered with hæmorrhages. The valves were healthy. The musculi papillares in the left ventricle showed fatty degeneration.

Microscopical appearances: The bone marrow from the tibia shows a striking leucoblastic reaction. The change is widespread, though rather more pronounced in patches. The cells present in these areas are lymphocyte-like cells, mostly of large size. The cell protoplasm is scanty, and at times forms may be seen as a narrow ring round the large nucleus, which is either irregularly rounded or oval. The cell protoplasm is non-granular, for the most part basophilic, but not a few cells show a tendency towards a neutrophilic reaction. The nuclei are for the most part degenerate, many showing a loose network with large clear spaces in between. There are a few myelocytes present, mostly of the coarsely granular eosinophilic type [illegible] phonuclear cells are [illegible] are distinct zones of [illegible] aloblastic in type. The nature of the lymphocyte-like cells is not clear, but I would regard them as myeloblasts or premyelocytes The liver is diffusely infiltrated with cells similar to those predominating in the marrow. These cells fill the capillaries and form large clusters in the portal spaces. The kidneys are similarly affected, but the infiltration is more patchy and best marked in the zone between the cortex and medulla. The tonsils show chronic inflammation, and the crypts are full of inspissated secretion or débris"

The main interest of the case is the simulation of spinal caries by leukæmia, for this does not appear to have been observed in any published cases. At any rate, it is not mentioned in the 121 summarised cases of acute leukæmia tabulated by Boudet.[8] It is known that occasionally the sternum and long bones are tender on pressure and exceptionally the site of dull pain, presumably from hyperplasia of the bone marrow and absorption of the bone. According to Muir,[7] these symptoms are relatively less rare in myeloid than in lymphocytic leukæmia. In Parkes Weber's[9] and Hans Leyden's[6] cases of acute leukæmia there was pain in the back. It is, however, noteworthy that in a case in which the bone marrow changes were confined to the vertebræ there is no mention of pain in the back (Emerson[4]). Chloroma is an atypical form of leukæmia characterised by the presence of green tumours usually growing from bones, and it is not surprising to find that pressure symptoms may occur. In the analysis of his collected cases of chloroma Dock[3] quotes two examples of pressure on the spinal cord and several of sciatica. In one of Treadgold's[8] cases (a boy aged 3 years) there was loss of power in the legs. There was a tumour on the right frontal bone, but no mention is made of the spine at the necropsy.

A puzzling feature was the very considerable enlargement of the liver and the absence of any splenic enlargement—a rather exceptional association in leukæmia and especially in this instance, as the spleen enlarges more readily in young than in adult subjects. It is not noted in any of Babonneix and Tixier's[1] 29 collected cases of acute leukæmia in infants; but among Forbes and Langmead's[5] 12 cases of acute leukæmia in early life there was one case (a boy aged 9 years) with enlargement of the liver without splenomegaly. In Wolff's[10] case of "aplastic leukæmia" with aplasia of the bone marrow, progressive anæmia reaching 500,000, leucocytes 3000 to 5000 with a predominance of large lymphocytes, the spleen was small and the liver reached six finger-breadths below the costal margin. The very considerable enlargement of the liver in our case shows that the leukæmia was not of the most acute form.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

NOTES OF THREE CASES OF QUININE POISONING, TWO OF WHICH WERE FATAL.

BY JOHN D. GIMLETTE, M.R.C.S. ENG., L.R.C.P. LOND.,
RESIDENCY SURGEON, KELANTAN.

LARGE doses of quinine, such as a scruple or half a drachm of the sulphate in a single dose, may occasion vomiting and pain in the stomach, giddiness, flushing of the face, palpitation of the heart, a sense of distension in the head, intense headache, ringing in the ears, numbness in the feet, deafness, blindness, and even delirium and coma. In persons who are susceptible a dose of 6 grains may, as reported by Connor,[1] give rise to these alarming symptoms, with a rash in addition, but such accidents are uncommon in the absence of any definite idiosyncrasy, and death as a direct result of a poisonous dose is rare and worthy of record.

On Sept. 9th, 1913, two Chinese coolies, employed on a small rubber estate in one of the Protected Malay States, died, and another was definitely poisoned at the same time but subsequently recovered. Malaria is prevalent in the district, and the value of quinine as a preventive is well known to Chinese immigrants; it is commonly administered to them after a preliminary dose of Epsom salts. At daybreak on the day in question the three Chinese reported themselves sick, with constipation and fever; they were attended to by their head man, a Chinese mandor, who gave them each 2 ounces of a concentrated solution of quinine in mistake for a solution of Epsom salts. The patients were not seen by any qualified practitioner, but as soon as it was recognised that they had been accidentally poisoned an Indian hospital assistant was sent for from a neighbouring estate. On his arrival, about 10.30 A.M., one Chinese was dead and another unconscious; he washed out the stomach of the latter and gave an injection of strychnine, but the man shortly died.

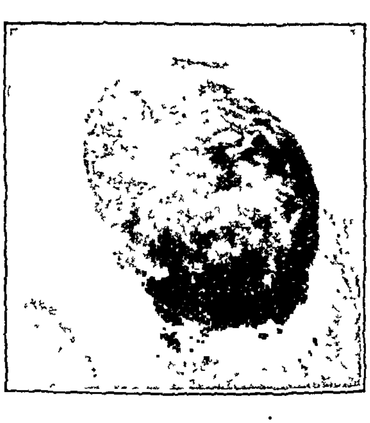
The third was groaning, sweating, vomiting, and only semi-conscious; he was given ipecacuanha as an emetic, as well as castor oil, and was removed to the nearest estate hospital. On his recovery the next day he said he felt giddy after taking the medicine, had ringing in the ears, fulness in the head, deafness, double vision, and then became delirious. When in hospital he complained of great itching in the lower limbs. The urine was not examined. The men who died had complained in Chinese of burning at the heart; they became delirious and ultimately comatose. It is roughly estimated that each coolie took 90 grains of sulphate of quinine in a single dose on an empty stomach.

Kota Bharu, Kelantan.

NOTE OF A CASE OF RAPIDLY GROWING ALVEOLAR SARCOMA OF THE CRANIUM.

BY D. W. KEILLER MOODY, M.D., C.M. ABERD.

A BOY aged 10 years was hit behind the ear by a small stone. As soon as it occurred he complained of much pain, and a lump about the size of a hazel nut was seen by the parents behind the ear. They did not attach much importance to it, and he went to school for three weeks afterwards, making no complaint. The lump, the parents said, remained the same size. He was then sent home one day from school as he had been "sick." The lump then began to swell. Medical advice was sought, and it was taken to be a hæmatoma that had "broken down." It was soft and fluctuating.



From a photograph of the growth showing the fungating mass protruding from the incision.

---

[1] Medical Record, April 4th, 1903.

A small incision was made, and it bled freely and a small quantity of pus exuded. It was then recognised that a mistaken diagnosis had been made, and that it was probably malignant. Pathological examination showed it to be an alveolar sarcoma, probably periosteal in origin. It grew to be an enormous size, embracing the whole of the left parietal bone, most of the temporal, and a small part of the frontal and occipal (see figure.) Cerebral symptoms set in, and the patient died exactly four weeks and two days from the time he became "sick," or seven weeks and two days from the time of the trauma.

The case is interesting, not only on account of the trauma, but because of the rapid growth and early fatal results.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Exhibition of Clinical Cases.

A MEETING of this section was held on Jan. 8th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. H. D. ROLLESTON and Mr. E. G. BOYD showed a case of Addison's Disease in a Boy, with Calcification of the Adrenals. The patient, aged 12¾, was bright, intelligent, and fair-skinned until the close of 1913, when his skin was noticed to be brown; an attempt to wash it off failed, and it was thought to be due to his habit of drinking vinegar. Synchronously with his change in colour he lost all energy, was inclined to sleep all day, very easily got tired, had a cough at night, and nocturnal enuresis. There had not been any gastro-intestinal disturbance or fainting attacks. An uncle and a brother were said to have had tuberculosis. On admission to the hospital the boy had a somewhat lifeless, sleepy, sunken-eyed appearance and a general bronzing of the skin, especially around the nipples and pudenda. There was a pigmented scar in the left groin, and the back and abdomen showed a few scattered spots of pigmentation. There was no buccal pigmentation. There were no signs of pulmonary or spinal tuberculosis, and von Pirquet's reaction was negative. The systolic blood-pressure in the arms varied between 74 and 84 mm. Hg. There was no valvular disease of the heart. There was no dulness behind the manubrium sterni. Dr. Stanley Melville reported that a skiagram showed very definite calcareous particles in the region of the last rib and suprarenal body on the right side, less definite on the left side. The heart was small and vertical. There were discrete and dense opacities at the hila of the lungs, suggesting calcified nodules. The movements of the diaphragm were feeble, but the expansion and translucency of the apices normal. A blood count showed some polycythæmia and an increase in white cells to 23,000 per c.mm. Dr. Rolleston said that a high lymphocyte count had been thought to indicate concomitant lymphatism, and therefore to be an ominous sign. An increased number of red blood corpuscles was occasionally seen in Addison's disease, and various explanations had been offered. It had been thought to be due to concentration of the blood from vomiting or diarrhœa, neither of which occurred in this case. A specific action of tuberculous toxin had been invoked, and G. R. Ward had described the process as compensatory, and argued that adrenal insufficiency gave rise to circulatory stasis, which, in its turn, caused concentration of the blood and actual increased blood formation. The treatment which was being adopted was rest in bed and adrenalin chloride solution (1 in 1000), 10 minims in water three or four times daily by the mouth.

Mr. SYDNEY BOYD showed a case of Splenectomy for Chronic Acquired Acholuric Jaundice with Splenomegaly. It was that of a man aged 22. The illness began in August, 1909, with lassitude, loss of appetite, indigestion, with occasional vomiting, especially after fatty foods, frontal headache, giddiness (especially on stooping), and slight icteric discolouration of the conjunctivæ and skin. Jaundice had persisted more or less since the onset and always became worse after exertion. The urine was dark in colour and the stools were said to be light-coloured. Eighteen months ago the gall-bladder was explored and drained in a London hospital with a negative result, the jaundice persisting. He first came under Mr. Boyd's observation in August, 1913, and was found to

There was slight

The spleen was

below the costal margin. The liver edge could be felt just below the right costal arch and was rather firmer than normal. The other viscera were healthy. The motions were of normal colour; the urine dark reddish-brown, specific gravity 1016, acid, contained an occasional trace of albumin, no sugar, blood, or bile. The red blood cells numbered 4,200,000 per cubic millimetre, white cells 5900, hæmoglobin 80 per cent., colour index 1·05. A week later the blood was examined by Dr. S. H. Browning, who reported as follows: Total red cells, not done; hæmoglobin, 96 per cent.; white cells, differential count (500 counted)—polymorphonuclears, 70 per cent.; lymphocytes, 28 per cent.; large mononuclears, 1·2 per cent.; eosinophiles, 0·8 per cent.; mast cells, 0. From the appearance of the films there was some polymorpho-leucocytosis. The red cells varied considerably in size; there was some polychromatic staining. No normoblasts were seen. Some poikilocytosis. Films stained by

some red cells and

serum was quite

is for bile pigment.

The blood, unfortunately, underwent auto-hæmolysis before it was spectroscoped. The relation between serum and clot was very abnormal—about 7½ c.c. of serum in 10 c.c. of blood. Wassermann's reaction was positive. There was a very slight increase of fragility of the red cells. The patient was kept under observation in bed for four weeks. The jaundice varied from day to day, and with each exacerbation he had drowsiness, headache, and general malaise. Operation: A preliminary hypodermic injection of morphine, scopolamine, and atropine was given. Inhalation anæsthesia by open ether was employed. Splenectomy was performed through a vertical incision near the outer edge of the left rectus. The spleen was delivered out of the wound, there being no adhesions to the diaphragm. The gastro-splenic omentum was divided close to the spleen between several pairs of forceps and ligatured. The splenic vessels between the two layers of the lieno-renal ligament were then similarly treated, being divided also close to the spleen. The wound was closed in layers without drainage. There was hardly any shock; very little vomiting and no hæmatemesis followed. Convalescence was rapid. On the third day after the operation the jaundice was very much less; at the end of a week the sclerotics had lost their icteric tinge and the urine was normal in colour. The patient expressed himself as feeling very much better, having lost his headache and drowsiness and digesting his food well. A second report on the blood was made by Dr. Browning one month after splenectomy. The Wassermann reaction was now negative, and Dr. Browning had little doubt that the former positive reaction was due to the excess of bile in the blood serum. The fragility of the red corpuscles was, as before, practically normal. The blood had not hæmolysed of its own accord. Hæmoglobin, 100 per cent; differential count normal; character of blood cells normal; the blood seemed normal. Dr. A. G. Gibson reported on half the spleen sent preserved. The external shape of the organ was normal and the size about twice that of the adult spleen. Its surface was slightly roughened, but the capsule was not definitely thickened. On section it was dark brown in colour, and the Malpighian bodies were marked though not increased in size or number. The trabeculæ could also be seen. Small darker points could be seen here and there and suggested thrombosis in the smaller vessels; some of the larger vessels were definitely thrombosed. Microscopically, the organ was highly cellular. Malpighian bodies were present and the larger trabeculæ were thickened. Red and white clot could be seen in some of the larger veins. In the more cellular parts were numerous lymphoid channels lined by a simple but not always regular epithelium.

—kinks in the ileum, uric acid, &c. Many cases of pernicious anæmia had been "cured" by divers remedies. The ordinary course of pernicious anæmias was three "cures" and three relapses. The study of the blood and its diseases had greatly altered during the past 20 years. It was only seven years ago that the myeloblast was discovered, and it revolutionised our ideas on blood diseases. He thought that Dr. Hunter's statement that the size of a septic lesion was of no importance was grossly inaccurate, and he begged the audience to temper their enthusiasm with judgment.

Mr. **ERNEST H. SHAW** said that the mouth of the average hospital out-patient was a fearful place. Swabs and cultures showed fearsome growths. Streptococci were *the* important organisms. Each culture really represented a group of streptococci. In pernicious anæmia he had never been able to find streptococci in the blood either ante or post mortem. The pus from pyorrhœa alveolaris on culture showed almost pure growths of streptococci, and it always seemed to him a rather doubtful procedure to pull out the teeth. He was no advocate for the indiscriminate use of vaccines unless the teeth had first been attended to and ordinary dental hygiene had failed to check the disease. He disagreed with Dr. Tidy's views on oral sepsis and tonsil operation and agreed with Dr. McKenzie. He could not agree with Dr. Hunter that pernicious anæmia was due to infection, as no organisms had ever been found in the blood. If Dr. Hunter's views were correct, how was it that one found so many filthy mouths in people who were in sound health and full-blooded?

The **PRESIDENT** thanked Dr. Hunter for his interesting address and for giving the society an opportunity to hear the result of his 25 years' labours on conditions of the blood. He quoted the case of a boy aged 14 who was at present under his care. He first saw the case on May 28th last, and was puzzled as to a diagnosis till the blood was examined, which revealed a typical lymphatic leukæmia; on June 7th the count showed 8000 white cells, 2,880,000 red cells, colon index 1·6, a very low polymorphonuclear count (namely, 16 per cent.), and a very high lymphocyte count (namely, 82 per cent.). Anxious to have another opinion Dr. Hunter was called to see the case, but the temperature, which had been running an erratic "high" course for a month, had dropped two days before Dr. Hunter was called in. Dr. Hunter advised the removal of an upper lateral incisor tooth which in itself was quite healthy, but the gum was a little spongy over its root. There was no pain, and no pus was present. To make sure that sepsis was not giving rise to the trouble a second tooth was removed so that the antrum could be examined. No pus was obtained. The President said that although the boy looked very well and had put on weight considerably he was still not right, and that the last examination of the blood, which was made on Dec. 24th, gave white cells 7000, red cells 5,920,000, colon index 0·7, the polymorphonuclears as 42 per cent., and the lymphocytes as 54 per cent.; the former should be between 60 per cent. and 70 per cent. and the latter about 25 per cent. Time would tell as to whether this was not a true case of lymphatic leukæmia or whether sepsis played a part in this severe illness.

Mr. **F. TALBOT** said that in most dental practices 80 to 90 per cent. of the patients had oral sepsis. It would be exceedingly difficult to prove that such an everyday cause produced such a disease as pernicious anæmia. One might as well say that the teeth ought to be extracted in case they harboured the pneumococcus, which it was known they did.

Mr. **A. H. PAYAN DAWNAY** said that for want of any better reason many cases of inflammatory eye diseases were put down to oral sepsis, and he could certainly say that many such conditions were greatly benefited by suitable dental treatment.

Mr. **GEORGE NORTHCROFT** said that when marked pyorrhœa existed there was no known cure save radical removal of the teeth. Mild cases of gingivitis might be successfully treated. Many cases of alimentary toxæmia and arthritis had been absolutely cured by the removal of the primary focus of infection in the mouth. It had seemed to him a disgrace that no other effective treatment than extraction had ever been discovered for severe oral sepsis.

Dr. **HUNTER**, in replying, thanked the society for the great interest they had taken in the subject, and he especially wished that all the medical men present would recognise the fact that "medical sepsis" existed and was of supreme importance.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

The Retraction Ring of Bandl.

A MEETING of this society was held on Dec. 19th, 1913, in the Glasgow Maternity and Women's Hospital, Mr. A. ERNEST MAYLARD, the President, being in the chair.

Dr. **R. JARDINE** read a paper on the Retraction Ring of Bandl as an Obstruction in Labour. From a clinical point of view, he said, the exact situation of the ring was not of so much importance as the fact that it did form and might cause an exceedingly dangerous obstruction in labour. In some cases it was not the primary cause but the result of the obstruction; in others, it was itself the cause of the obstruction. While it was a rare complication of labour, it was commoner than was generally supposed. Cases fell into three groups according as the retraction ring formed (1) in front of the presenting head, (2) above the presenting head, or (3) in breech presentations; and each group presented the following characteristics: 1. Retraction ring in front of the head. *Diagnosis.*—There was no apparent obstruction to the advance of the head, yet labour was delayed, though the uterine contractions were strong and frequent. On palpation of the abdomen the head was found well above the brim of the pelvis and could not be pushed down. If the abdominal wall were thin the ring could be felt, but with a thick wall it might not be felt. On vaginal examination the os was found to be dilated and the lower uterine segment opened up, but some 3 inches or so above the os a distinct ridge was felt running round a portion or the whole of the uterine cavity in front of the head. During a pain this ledge did not relax but became more prominent and prevented the advance of the head. The membranes might or might not be ruptured; if intact, they protruded into the vagina and might even appear at the vulva. In any case the ring undoubtedly formed before the membranes ruptured. The cause of the formation of the ring was possibly a spasmodic contraction of certain of the uterine fibres, comparable to the spasmodic contraction of the os which was occasionally met with and was generally attributed to an irritant which acted reflexly. *Prognosis.*—If the condition were recognised in time both mother and child should be saved, but unfortunately in many of the recorded cases a definite diagnosis was made only when exhaustion had set in and there was little chance of saving either. The proper *treatment*, if the child were alive, was Cæsarean section. Full doses of morphia or opium failed to cause relaxation. Manual dilatation was impracticable. Incision of the ring would be followed by extension of the incisions and would end in rupture of the uterus. Hydrostatic bags could not be introduced high enough to bear on the ring. If the child were dead it could be delivered by craniotomy. 2. Retraction ring above the presenting head. *Diagnosis.*—In a thin patient the ring would be palpable, and on vaginal examination it could be felt as a distinct ledge in front of the shoulders. The membranes ruptured before there was any dilatation of the os and the uterus soon became moulded round the child. During the slow dilatation of the os retraction took place and the ring formed round the neck of the child. *Prognosis.*—If the condition were recognised early the chances for both mother and child should be good, but if it were recognised only after attempts to deliver had failed the prognosis was unfavourable, especially for the child. In this group of cases, also, the treatment was Cæsarean section if the child were alive, or craniotomy if it were dead. 3. In a breech presentation, when the legs were extended, impaction generally occurred, because of the retraction ring gripping the child below the knees, so that its legs and feet were hitched above the ring. In these cases the membranes ruptured early, the whole of the liquor amnii drained away, and the uterus became moulded round the child. The risks to the mother were very small if proper precautions were taken, and to the child they were not much greater than in an ordinary breech presentation which required artificial delivery. With the patient deeply anæsthetised the flattened hand should be passed in carefully in front of the child until a foot was reached, which must then be swept inwards over the front of the child and brought down carefully on account of the thinness of the lower uterine segment. When the leg was brought down traction should be made upon it, while an assistant kept up firm pressure upon the fundus of the uterus to prevent the arms going up and to keep the head well flexed. If the arms were caught they must be relieved by sweeping them over the front of the child, and the after-coming head must be dealt with in the usual way.

Reviews and Notices of Books.

The Examination of Waters and Water-supplies.

By JOHN C. THRESH, D.Sc. Lond., M.D. Vict., D.P.H. Camb. Second edition. With 53 illustrations. London: J. and A. Churchill. 1913. Pp. 644. Price 18*s.* net.

DR. Thresh's experience of this great subject is well known to be a wide one. He wrote authoritatively on water and water-supplies a good many years ago, and his views as to the ways and means of securing pure supplies have borne fruit and have been a useful guide to many municipal authorities. From the point of view of securing a pure and abundant supply of water, he was amongst the first to appreciate the importance of studying the topography of water-supplies, and at the same time devoted much attention to the consideration of the technical problems which presented themselves in regard to differentiating those waters which were suitable and unsuitable for drinking purposes by both chemical and bacteriological methods. His book reflects this work, and the second edition of it will be welcomed. The previous edition was issued in 1904, and of course since that time considerable and important developments in connexion with questions of quality and quantity of water-supply have occurred. The work has been brought into touch with these newer developments.

Dr. Thresh discusses at greater length than before, and in the light of recent researches, the extraordinary importance of the processes of self-purification, chief amongst which is sedimentation. Storage in the case of London's water-supply has undoubtedly been largely responsible for maintaining a pure and abundant supply since the days not so many years ago when there were reasonable complaints of shortage and of doubtful quality. The huge schemes of reservoir construction at Staines and Tottenham prove to have provided not only an adequate supply of water by reserving the heavy flow of flood time, but also to have maintained that reserve in a condition fit for drinking owing to the purification that ensues when water is stored for a definite period. No one has more fruitfully developed the question of the great advantages of storage than Dr. A. C. Houston, the present water examiner to the Metropolitan Water Board, whose valuable contributions also on the bacteriology of water-supplies are cordially appreciated by Dr. Thresh. Dr. Thresh has, indeed, drawn most usefully upon the series of researches carried out by Dr. Houston, and no reference could be more important than that on the numerous investigations which Dr. Houston carried out on a large scale on the effect of storage. This will be understood when we quote one amongst the many conclusions arrived at, which is as follows: "The habitual use of stored water would lighten the grave responsibilities of the Water Board as regards the safety of the London water-supply, and would tend to create a sense of security amongst those who watch over the health of the metropolis."

Dr. Thresh's book will be valued, not only for his clear discussion of the practical considerations involved in supplying pure and abundant water to the community, but also on account of the chapters on laboratory technique, which provide a system of scientific control over that supply.

Diagnosis and Treatment of Diseases of Women.

By HARRY STURGEON CROSSEN, M.D., Associate Gynæcologist, Washington University Hospital; and Associate in Gynæcology, Washington University Medical School. Third edition. With 744 engravings. London: Henry Kimpton. 1913. Pp 1025. Price 28*s.* net.

THE third edition of this book retains the characteristics of the first two editions. It has been revised and much new material added, as well as some new illustrations.

A description is given of Abderhalden's serum-diagnosis of pregnancy, which the author considers may be used to advantage in a number of classes of cases, if its limitations are borne in mind. The method of employing the complement-fixation test in cases of gonorrhœa in which the gonococcus cannot be demonstrated is described, and in the opinion of the author the diagnosis may be cleared up with fair certainty in many doubtful cases of this kind by this test, provided the work is carried out by a well trained observer. An interesting section of the work is that dealing with the use of various forms of pessaries not usually described in text-books of gynæcology, which are of value in cases of inoperable prolapse of the uterus and vagina. The author describes the methods of using the Gehrung pessary, often a most useful support, Hewitt's pessary, that of Menge, and the cup and stem. The advantages of Gehrung's pessary are recognised by Dr. Crossen, and he gives a full account, with a number of useful diagrams, showing how to introduce this pessary and its action when properly placed in the vagina. It is certainly, as he says, the best of these pessaries and usually acts well in cases considered for one reason or another inoperable. In view of the fact that the preface to this edition is dated July, 1913, it is interesting to notice the statement in connexion with the treatment of cancer of the uterus that "the effect of radium treatment is practically *nil*," an interesting commentary upon the rate at which methods of new treatment may come into vogue. In not a few hospitals at this date (the beginning of 1914) the use of radium is to a large extent supplementing the knife in the treatment of cancer of the uterus.

The book is a good one, and this new edition should meet with a ready appreciation.

Die Cystenniere, Studien über ihre Pathologische Anatomie.

Von O. BERNER, Prosektor der Histologie an der Kgl. Frederiks-Universität zu Kristiania. Mit 159 zum Teil farbigen Abbildungen und 26 Tafeln. Jena: Gustav Fischer. 1913. Pp. xliii. + 284. Price 25 marks.

THIS work on cystic kidney is one of those

"Fridtjof Nansens Fonds" is duly thanked by the author for his liberal contributions towards the expenses of the preparations and the microphotographs.

Cystic kidney is not a very common affection and is one not often diagnosed during life. It is a condition, however, which has great interest for the wide and varied experience at home and abroad, possessing all the necessary qualifications for the preparation of a handbook of tropical medicine and hygiene. Dr. Daniels in the first edition grouped the diseases of the tropics according to their known or probable causation. Subsequent experience, he now says, has quite justified this method of grouping these maladies. In deference to certain criticisms passed upon the first edition, he has altered the arrangement of some of the matter so as to diminish the amount of repetition. The chief diseases dealt with in Part I. are malaria, blackwater fever, piroplasmosis, yellow fever, sleeping sickness, the various forms of leishmaniasis. the diseases associated with spirochætæ, and lastly intestinal protozoa. The concluding chapter is especially devoted to giving a *résumé* of prophylaxis in protozoal diseases. Dr. Daniels holds the opinion that most medical men working in the tropics ought to be practical sanitarians as well as clinicians; for this reason, while paying due attention to the clinical characters of tropical maladies and to their proper treatment, he gives special prominence to the etiology and prevention of these diseases.

This book gives in a handy and concise form a great deal of valuable information to practitioners and students of tropical medicine.

Handbuch der Vergleichenden Physiologie.

Herausgegeben von HANS WINTERSTEIN. 38. Lieferung. Band III., Physiologie des Energiewechsels. Erste Hälfte. Jena: Gustav Fischer. 1913. Pp. 1295–1446. Price 5 marks.

IN this part R. F. Fuchs continues his lucid and voluminous exposition of the colour changes and chromatic cutaneous functions of animals, more especially of the arthropoda. The work of Keeble and Gamble is often referred to. A very full account is given of the chemistry and movements of pigments of the chromatophores and of the various conditions which influence their activity, as well as the nerve endings and development of the chromatophores. A particularly full account is given of the physiology of colour changes in crustaceans. About one-half of the text is devoted to the cutaneous colour changes in fishes, amphibians, and reptiles. This is undoubtedly the standard work of reference in all matters relating to the fascinating subject of colour changes in animals.

Organic and Functional Nervous Diseases: a Text-book of Neurology.

By M. ALLEN STARR, M.D., LL.D., D.Sc., Ph.D., Professor of Neurology, Columbia University, New York. Fourth edition, thoroughly revised. Illustrated with 323 engravings in the text and 30 plates in colours and monochrome. London: Baillière, Tindall, and Cox. 1913. Pp. 970. Price 25*s.* net.

THE fourth edition of this deservedly popular text-book has been enlarged by some 60 pages, and has been brought thoroughly up to date. The space allotted to functional diseases of the nervous system has been more than doubled. There is new material in the sections on tumours of the brain, pellagra, headache, disorders of sleep, the sympathetic nervous system—to enumerate but a few. Several of the criticisms advanced in our review of the third edition have been noted, as their occasion has been removed. In view of the adherence given to Freud's theories in America it is agreeable to note the unmistakable attitude of reasoned scepticism adopted by Professor Starr. While admitting the elements of truth in the Freudian hypothesis, he emphasises the errors, demonstrates the limited scope of the Freudian methods of treatment, and exposes its objectionable features.

The text-book has been improved by the addition of new matter and the revision of the old, and again we can recommend it to the favourable notice of the medical profession.

LIBRARY TABLE.

Lectures on Tuberculosis to Nurses. Based on a Course delivered to the Queen Victoria Jubilee Nurses by OLLIVER BRUCE, M.R.C.S. Eng., L.R.C.P. Lond., Joint Tuberculosis Officer of Essex. London: H. K. Lewis. 1913. Pp. 134. Price 2*s.* 6*d.*—The material in these lectures has been chosen with discretion and is discussed plainly. The directions as to treatment and prophylaxis can be easily understood and acted upon by nurses in charge of patients suffering from tuberculosis, especially pulmonary. Abstruse theoretical subjects are avoided, but a good account is given of the channels of infection, and a few remarks are added on the chief points concerning immunity. We cannot agree with Mr. Bruce that the practice of training a nurse to examine patients with the stethoscope is "perhaps to be recommended." The nurse's province is to carry out the physician's instructions, not to encroach upon the field of diagnosis. The remarks upon social conditions. hygiene of the nursery, and the general care of a consumptive patient, especially as regards the disposal of the sputum, should be carefully studied by nurses in whose hands the prophylactic measures to be adopted largely lie. Sanatorium treatment is well described. The theory of auto-inoculation is discussed, and the "graduated labour system" is explained in detail. This is very necessary. The word "graduated" appears sometimes to be forgotten; if a patient is at once put upon active work in the garden without passing through the previous grades the result is often anything but favourable to the patient. Short descriptions are provided of the principal complications of pulmonary tuberculosis, and directions are given as to the nursing of such cases. There is at present a considerable demand for nurses in connexion with the National Insurance Act, and we can recommend this small volume as a reliable guide to instruct and assist those nurses in their duties.

Grundriss der Pharmakologie. Von O. SCHMIEDEBERG. 7. Auflage, bearbeitet unter Mitwirkung von E. ST. FAUST. Leipsic: F. C. W. Vogel. 1913. Pp. 643. Price, paper, 12 marks; bound, 13.40 marks —The rapid advances of pharmacological science render the revision of the text-books upon it an almost constant necessity. The first edition of the book before us was issued as far back as 1883. Up to 1895 three editions were issued, and as the present is the seventh edition, four more have been issued in the interval, that is between that year and the present time. The book shows careful revision throughout, and the references to modern literature are copious. The need, however, for further work is in some cases indicated in those references which bear a relatively early date. The work is divided into three sections. The first, on nerve and muscle poison, claims more extended treatment than the rest. It is subdivided into five groups: A, nerve and muscle poisons of the fatty acids; B, nerve and muscle poisons included in the alkaloid family; C, poison derivatives of the aromatic series; D, poisons of the camphor and terpene group; and E, the poisons of the toxin series (digitalin, picrotoxin, sapotoxin). Section II. includes considerations of drug, vehicle, aromatics, bitters, and so forth; while Section III. deals with neutral salts, alkalies, the metals and their salts. This last section contains interesting and up-to-date references to that increasingly important group of bodies, the metal colloids. The classification adopted is as convenient as any, and on the whole presents a clear and systematic view of the "foundations."

Synopsis of Midwifery. By ALECK W. BOURNE, B.A., M.B., B.C. Cantab., F.R.C.S. Eng. Bristol: John Wright and Sons, Limited. 1913. Pp. 212. Price 5s. net.—*This handbook is intended to present* the principal facts concerning obstetrics in such a form as to be useful to students preparing for their examinations. The book is to be used mainly for purposes of revision in conjunction with the ordinary more detailed text-books dealing with the subject. Important things from the examination point of view have been emphasised and a good deal of space has been devoted to treatment. The book should perform a useful function if used for the purpose for which it is intended; and based as it is upon the best-known text-books its teaching is not likely to lead the student astray.

MISCELLANEOUS VOLUMES.

OUR selection of volumes this week is truly miscellaneous, embracing biography, travel, antiquarianism, occultism, and food and cookery.

Mr. ARNOLD HAULTAIN, who appears as Boswell to Professor Goldwin Smith's Johnson, has given us in *Goldwin Smith, His Life and Opinions* (London: T. Werner Laurie, Limited. Pp. 304. Price 18s. net.), a most interesting book, though it is a misnomer to call it a "Life." But the "Conversations and Comments," which cover the period 1898–1910, show the Sage of Toronto as he really was—his brilliancy, his grim sense of humour, and, we must add, his extraordinary facility for being disagreeable in print. Like Johnson, he was a good hater, and the special objects of his dislike were the Jews in general and Disraeli in particular. The latter had called him "a wild man of the cloister," a phrase which Mr. Haultain considers not altogether inapt, and illustrates by saying that Goldwin Smith, when talking about some strikes, said: "Why cannot people be satisfied with what they have got?" At this time, says Mr. Haultain, his own capital was about £160,000. But no one can read Mr. Haultain's interesting and capitally written book without feeling that Goldwin Smith, despite his many limitations, was always absolutely sincere, and a truly great man.

From the ecclesiological point of view Spain equals if it does not surpass Italy, apart from Rome. Nowhere else has the primitive arrangement of the choir survived in such completeness as in Spain, where in the marvellous and gorgeous choirs of Seville, Granada, Toledo, and Burgos, to name only a few, may be seen the full development of the little embryo, such as the arrangement of San Clemente at Rome. In *The Cathedrals of Southern Spain* (London: T. Werner Laurie, Limited. Pp. 248. Price 6s. net) C. GASQUOINE HARTLEY (Mrs. Walter M. Gallichan) has written a book which should be read by everyone who is about to visit Spain. She writes with the mind of an artist, and as one who realises all that the Church meant and means to a Spaniard, and she is fully impressed with the dignity and richness of Spanish ritual. Sometimes her admiration goes beyond that which we can feel—for instance, in the matter of Spanish glass and windows. They are, it is true, eminently fitted for the climate as regards size and position, and the glass is often beautiful in colour, but when she says (p. 197), "In Barcelona as in Seville Cathedral one feels that one has never seen church windows before one visits Spain," we can only wonder whether she has ever seen Le Mans or Chartres. But we are quite of one mind with her in her insistence on the richness and sumptuous character of a Spanish cathedral. There is nothing like it elsewhere in Europe, except in the great churches of Russia, both monastic and diocesan, such as the two great churches in Kieff. The same feeling for dignity and richness which led the Spanish Church to fight for and maintain the Mozarabic Liturgy (even though it be used only at Toledo) is apparent in the arrangement and decoration of her churches, although even in them the "foul torrent of the Renaissance," to quote Ruskin's characteristic exaggeration, brought forth the monstrosities of Churriguera. Mrs. Gallichan's book is carefully illustrated with reproductions of photographs which add to the interest of the descriptions. In one place, however (p. 206), the account given in the text of the Puerta de Las Infantas, at Lerida, does not seem to us to tally with the picture thereof.——Sir FREDERICK TREVES'S *Land that is Desolate* (London: Smith, Elder, and Co. 1913. Pp. 287. Price 6s. net.) received an extended notice on publication, in THE LANCET for Jan. 25th, 1913. It is therefore unnecessary to do more here than to call attention to its republication in a popular edition.

Personal Experiences in Spiritualism, by HEREWARD CARRINGTON (London: T. Werner Laurie, Limited. Pp. 274. Price 7s. 6d. net), is a most amusing and instructive work. Mr. Carrington is interested from a scientific point of view in so-called "spiritualistic" phenomena, and has come to the conclusion that "98 per cent. of the phenomena are fraudulent." He is, on the other hand, convinced that mediums presenting genuine manifestations can be found, and that Eusapia Palladino is one of these. The latter half of his book is devoted to an account of Eusapia's American *séances*. His theory is that the phenomena are due to some force which emanates from her, or from some intelligent will other than hers but manifested through her. His book concludes with a plea for the foundation of a psychical laboratory on the lines laid down by Sir Oliver Lodge in a paper contributed to the *Journal of the Society for Psychical Research* in 1894. The subject certainly needs more investigation. The first part of the book is an account of Mr. Carrington's investigations into various spiritualistic phenomena, which were all proved fraudulent. They form extremely entertaining reading, but it makes for sadness to learn that our race numbers among its members those who can exhibit, as do the believers in these phenomena, such foolish credulity. And one of them was judge of a Probate Court!

Amateur collectors of old furniture, old pottery and glass, embroideries, and so forth, will doubtless revel in *First Steps in Collecting* (London: T. Werner Laurie, Limited. Pp 324. Price 3s. 6d. net), in which GRACE M. VALLOIS chats discursively of "Chippendales" and "Adamses," and
"Sheratons
turning, of
and many c
There is in
anecdote a
chests receive attention, and some quaint recipes are quoted, notably a preventive against the plague (p 311), which consisted of "a quill as is filed up with quicsilver and sealed up with hard waxe and soed up in a silke thinge with a string to ware about your neck." It was not free from danger, though, being "nitty" and liable to affect "one's teth and eies" unless "corked up fust and then seled."

Rearing an Imperial Race. Edited by CHARLES E. HECHT, M.A. (London: Published for the National Food Reform Association by the St. Catherine Press. 1913. Pp. 508. Price 7s 6d. net.)—We commented in THE LANCET of Sept. 14th, 1912, on the proceedings at the Second Guildhall School Conference on Diet, Cookery, and Hygiene held in May, 1912. This volume consists of a full report of those proceedings, to which are added extracts from reports of medical officers of health, reprints of various articles which have appeared in the press, articles on diet by school and other medical officers, accounts of the methods for feeding school children in the United States, France, Switzerland, and Germany, and notice of the objects and methods of the National Food Reform Association. The book contains much useful information, to which is supplied a very full index, and will be found of value in view of the forthcoming Education Bill. ——*Mrs. Edwards's Cookery Book* (London: T. Werner Laurie, Limited. Pp. 303. Price 6*s.* net) covers a large area, giving many excellent recipes, which, however, are not always quite clear, even to an experienced cook. Joints, turkeys, and suchlike are often directed to be roasted for a definite length of time irrespective of weight, and so on. The author's methods are quite different in many respects from those ordinarily accepted, but in judicious hands much could be done with them. There are some good bills of fare for households of varying capacities and recipes for drinks and invalid cookery. The domestic remedies are of a simple household character, and with the exception of one cough mixture containing laudanum appear unexceptionable.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

(1) KEFIR SALIÈRES; (2) EXOL (COGNÉT); (3) AGONOL (COGNET); (4) HEPASUINE ELY; AND (5) ZOMYO BEEF.

(AGENCY: ROBERTS AND CO., 76, NEW BOND-STREET, LONDON, W.)

THESE five French pharmaceutical preparations are all of interest. 1. This kefir, or effervescent sour milk, is prepared after the formula of M. Ch. Salières, which aims at excluding foreign or contaminating bacteria. In other words, the preparation is a culture of a pure ferment or lactose yeast. According to our analysis the kefir has the following composition:—Total solid matter, 4·10 per cent.; protein, 2·64 per cent.; lactic acid, 0·35 per cent.; milk sugar, traces; fat, 0·16 per cent. It is primarily intended for diminishing the activities of the gastro-intestinal flora on the lines laid down by Metchnikoff. It is a satisfactory preparation for the purpose. 2. Exol is an elegant combination of calomel, santonin, and thymol, contained in glutinous globules, which is suggested for use as a specific in the treatment of ankylostomiasis. We had no difficulty in determining the presence of the medicaments indicated. 3. Cognet's agonol is described as a neutral benzoic ether of santalol which surrenders in the body its constituents in a nascent and therefore very active form. It is stated to be destructive of both the gonococcus and its toxins. 4. Hepasuine ely is described as containing all the active medicinal and organo-therapeutic principles of cod-liver oil. It is prepared in the form of an extract from pig's liver. The extract is combined with a syrup of sugar. We found present traces of biliary acids, a decided amount of iodine, arsenic in organic combination (sodium methyl), and hypophosphites. It has uses in connexion with the treatment of tuberculosis and also in disorders of the liver and bowels. 5. Zomyo beef is a clear brown fluid said to be made with beef juice and glycerophosphates. We found present 22·8 per cent. of soluble matters. Amongst these protein amounted to 13·13 per cent. and mineral matter to 5·75 per cent. The mineral matter consisted largely of phosphates derived from the glycero-compound. Its use is indicated in those disorders in which general nutrition is impaired. A large quantity, however, would have to be administered before any appreciable amount of nutrient was given. It is a pre-digested beef preparation containing chiefly albumose and peptone.

IODEX PESSARIES.

(MENLEY AND JAMES, LIMITED, MENLEY HOUSE, 39, FARRINGDON-ROAD, LONDON, E.C.)

The employment of iodine in gynæcological practice has been limited owing to the irritating character of the ordinary preparations. In association, however, with a bland fat, it is stated that iodine can be introduced in the form of a pessary, with satisfactory results. The pessary is contained in an easily soluble gelatine envelope which serves to prevent impairment of the iodine value. On the contents being distributed the iodine is yielded in the free state ready to exert its antiseptic and healing properties. Each pessary contains 2½ grains of free iodine regularly distributed in a neutral base which melts at the body temperature.

EUMENTHOL TOOTH POWDER.

(HUDSON'S EUMENTHOL CHEMICAL CO., LIMITED, SYDNEY, AUSTRALIA. LONDON AGENTS: F. NEWBERY AND SONS, LIMITED, 27 AND 28, CHARTERHOUSE-SQUARE, E.C.)

This tooth powder is designed on sound principles and is very agreeable to use. The distinctive feature about it is that in addition to some approved germicides it contains magnesium peroxide which readily parts with free oxygen, as our experiments have shown. This probably leads to a favourable cleansing action upon the mouth and a slight whitening effect upon the teeth. The powder is finely divided and is free from harmful constituents and gritty substances. Analysis showed that the powder was capable of giving off oxygen equal to 1 cubic centimetre per gramme. This disengagement of oxygen leads to the formation of a pleasant and wholesome foam.

SOLUTION OF DIGIPURATUM.

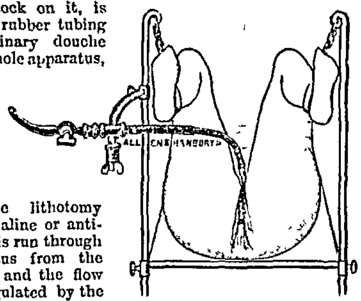
(KNOLL AND CO., 8, HARP-LANE, LONDON, E.C.)

We have referred to digipuratum on a previous occasion, when we pointed out that it was a physiologically standardised preparation of digitalis in which the undesirable principles of the plant had been eliminated and the principles of known activity retained. The solution is, further, stable. It is intended for administration only by the mouth. In order to measure accurately the dosage in *drops* a small bent glass rod is placed in the neck of the bottle. The rod terminates outside in a rounded end, while the end inside is flattened so as to prevent the rod from falling out. This is a very convenient and simple method of obtaining a regular flow of uniformly sized drops.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. Hüpeden, of Hannover, an author of various treatises on medical politics, aged 85.—Dr. Ervin Miensowicz, *privat-docent* of medicine in the University of Cracow.—Dr. John Green, formerly professor of ophthalmology in the George Washington University Department of Medicine, Washington.—Dr. Franz, of the Government laboratories, Berlin, formerly of the Physiological and Pharmacological Department of the Imperial Sanitary Office, aged 35.—Dr. Berthold, an eminent Carlsbad physician, who was at one time in practice in London. Many Royal and distinguished persons were amongst his immense *clientèle*.—Dr. E. Guillet, clinical professor of surgery in the Caen Medical School.—Dr. Antonino D'Antona, clinical professor of surgery in the University of Naples.—Dr. L. Kessler, extraordinary professor of gynæcology and obstetrics in the University of Iurieff (Dorpat).

New Inventions.

PERINEAL SPRAY OR DOUCHE.



THIS consists of a flexible metal tube made of pewter which can be easily bent into any fixed position. To one end of this tube is attached a small piece of rubber tubing carrying a glass nozzle, while the other end, which has a stopcock on it, is attached by rubber tubing to the ordinary douche can. The whole apparatus, which can be readily sterilised by boiling, is attached by means of a sliding bracket to one of the lithotomy uprights. Saline or antiseptic fluid is run through the apparatus from the douche can and the flow is easily regulated by the stopcock. If the operation is in the region of the anus the pewter tube is so bent that the glass nozzle points downwards and impinges on the central point of the perineum. If the operation is on the vulva the nozzle is fixed just below the symphysis pubis. From these points the regulated stream of fluid washes away all blood, gives the surgeon a clear view of the field of operation, and saves an assistant from constantly swabbing the wound, and to a certain extent injuring the tissues. It has been found especially useful in operating on hæmorrhoids by Whitehead's method. This apparatus, which is shown in the illustration, was designed by me five years ago at the request of the late Sir Frederick Wallis. It has been in use at St. Mark's Hospital since that time and has given the utmost satisfaction. Care must be taken in bending the pewter tube to do so always at the nozzle end and not near the joint at the bracket.

The apparatus is made by Messrs. Allen and Hanburys, Limited, Wigmore-street, London, W.

Harley-street, W. H. GRAEME ANDERSON, F.R.C.S. Eng.

DECEMBER, 1913, AT HOME AND ABROAD.

The Weather at Home.

UNTIL after the middle of the month the weather was unusually mild for the time of the year throughout the British Islands, the wind being constantly between south-west and west, and often blowing a gale on various parts of the coast and sometimes with considerable force inland. During the latter part of the period, however, the wind shifted round to north-west and north, and very occasionally died out altogether, the effect on the temperature being most marked. In the northern half of the kingdom the frost was intense, and in the south and south-east the thermometer [illegible] degrees below the freezing [illegible] for the whole month was, [illegible] December in almost all parts of the kingdom. A mild December generally means a wet one, but last month formed an exception, as the total rainfall was below the normal, the deficit being very large in many districts. In the metropolitan area, at K[illegible] was 45·5°, in excess [illegible] minimum was 38°, [illegible] ht saw the sheltered thermometer rise to 50° or above on several occasions, the highest figure being 54° on the 12th, but after the 22nd it seldom rose to 40°, and the minimum readings were mostly below 32°, the lowest of all being 28° on Christmas morning. The rainfall, which was just below an inch, fell on 14 days, and was just an inch below the normal, while the sun, which only shone *on 14 days, yielded* a total of 41 hours, an excess of 5 hours. Nottingham and Bath were both nearly 2° colder at night than Kew, and the former was slightly colder during the daytime also. Bath, however, *with a mean maximum of 47°, had warmer days than* the metropolitan station. The extreme south-west of England maintained its reputation for mildness and equability. At Newquay the mean maximum was 48·2°, and the mean minimum 42·7°, while at Torquay the corresponding figures were 49° and 41·5°. The Scilly and Channel Isles were milder *still. At both places the mean afternoon* maximum was 50° and the mean minimum of the nights about 43°. The south coast, as represented by Brighton and Bournemouth, had a mean maximum of 47°, while the minimum was 40° at Brighton and 39° at Bournemouth. The duration of sunshine varied a good deal in different parts of the kingdom. In the Midlands there was little, the figure at Nottingham being only 15 hours, or no more than half the normal, but Bath had 45 hours, Newquay 47 hours, and Scilly 41 hours. Brighton, Jersey, Torquay, and especially Bournemouth, were more sunny, the general figure being about 55 hours, and that at Bournemouth exceeding 60 hours. The rainfall varied considerably in the south-west. At Torquay, where the total was 2·1 in., there were only nine rain days, but at Newquay the total equalled 3·9 in., and was contributed by as many as 18 days. Scilly had 20 rain days, giving an aggregate of 3·9 in., and Jersey 15 days, with a total of 3·5 in. All these totals are below the normal, that at Torquay being 2 in. below. The frost at the end of the month was felt along the south and south-west coasts generally, but at Scilly and Jersey the sheltered thermometer fell no lower than 33°.

The Weather Abroad.

On the continent the weather was not cold for December, but colder than in the south and south-west of England. At Paris, Brussels, and Berlin the mean maximum temperature was 42° or 43°, and the mean minimum 33° at Paris, 34° at Brussels, and 35° at Berlin. The most severe frost was experienced in the eastern and central parts of France. At Paris the thermometer in the screen descended to 18° on the 22nd and 23rd, and to 22° on the 24th and 31st, and at Brussels it went nearly as low on the same dates. Berlin, however, was not so cold, the lowest temperature being 21° on the 19th. Berlin was, nevertheless, more wintry at the end of the month, when an unusually heavy fall of snow occurred. During the month as a whole Berlin had been rainy, the gauge yielding at least as much as 0·04 in. on no less than 20 days, amounting to an aggregate of 4·6 in. At Paris, on the other hand, there were only eight days with rain, giving a total of 2·6 in., and at Brussels 18 days, with a similar total. Many days at the French capital were sunless, and the total number of hours for the month was no more than 46 hours. The extreme south-east and south-west of France, as represented by Nice and Biarritz, were colder at night than the south-west of England, both resorts having a mean minimum temperature of 40°. The days were, however, warmer, the mean maximum at Nice being 54° and that at Biarritz 49°. Neither place entirely escaped the frost at the end of the month, although its visitation was transitory. At Nice the month generally was bright and sunny. Only six days brought rain, and the total fall was no more than 0·7 in., but at Biarritz rain fell on twice as many days and gave a total three times as large. Throughout Italy the weather was mostly fine, but frost was experienced at times as far south as Rome, and the temperature of the northern half of the country was usually lower than on the Riviera. Even Naples had some cold days, although as a rule the temperature was about midway between 50° and 60° during the afternoon. Madeira remained unaffected by the cold snap that visited the south of Europe. At Funchal the sheltered thermometer rose to 70° or higher on no less than 18 days, and fell no lower than 57° on as many nights. The mean maximum temperature was as high as 69° and the mean minimum 57°. The weather was also very fine as well as warm. *On only* five days was there rain, and the total fall, 2·0 in., was nearly all contributed by the 21st and 26th. Comparing the December mean temperature with that in the south of England, it may be said that Funchal was as warm as Brighton is in an average June during the day, and about as warm as an average July at night.

FOURTH ANNUAL MEETING OF CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA.

(Concluded from p. 131.)

ON Nov. 12th Dr. J. M. T. FINNEY, of Baltimore, read a paper on

Pyloroplasty.

During 14 years in which he had practised it, he said the immediate as well as the final results had been most encouraging. Although gastro-enterostomy and gastrectomy had a greater vogue, he believed that the simplicity and satisfactory ultimate results of pyloroplasty constituted it a safe and useful procedure.

The Treatment of Cancer.

On Nov. 13th Dr. THOMAS S. CULLEN, of Baltimore, read a part of the report of the Cancer Campaign Committee of the United States. He prefaced his remarks by saying that few surgeons had sufficient radium to give it a thorough trial, for extensive doses sometimes cured when smaller ones had little effect. Dr. Cullen advocated the standardisation of radium. Only time would show the extent of its utility. Surgery at present offered the best chance of cure. Instruction of the people in the nature of cancer would lead them to seek surgical aid. In this work the lay press had rendered good service. He urged the extension of lectures in women's clubs, factories, and elsewhere, the keeping of accurate records, and analysis of hospital statistics. Surgical pathologists must aid in diagnosis, and radical operation on diagnosis be urged. The frequency of uterine cancer was emphasised and its symptomatology discussed. Permanent relief followed operation in from 20 to 25 per cent. of cancer of the cervix, and in cancer of the fundus two-thirds were cured. These successful results would be greatly increased when women learnt to understand their condition and submit to early operation.

Dr. EDWARD REYNOLDS, of Boston, spoke of the American Society for the Control of Cancer—a body composed of prominent medical men and influential laymen. It was perfecting an organisation of national scope for the enlightenment of the public. It had already been guaranteed the large amount of money necessary. It intended to coöperate with all the existing organisations in the study of cancer.

Dr. FREDERICK R. GREEN, of Chicago, read a paper on the Education and Publicity of the Campaign by means of the Council of Health and Public Instruction of the American Medical Association. He said that the first thing was to interest the public, and especially the wealthy and influential public, in the problem of the control of cancer. The second necessity was the careful investigation of the entire problem of cancer. There was to-day in the records of the different hospitals of the United States an enormous mass of undigested material on the subject. The third requirement was the distribution to the public of the results of such an investigation. This was obviously a task for the *Council of Health and Public Instruction* of the American Medical Association.

On Nov. 14th Sir W. ARBUTHNOT LANE gave some further observations on

Intestinal Stasis.

He referred to the circumstances which led him to remove sections of the large bowel for chronic intestinal stasis. This condition, he said, was one of the most formidable causes of misery. Several patients had attempted to commit suicide on account of it, and in all such cases the removal of the large bowel had restored the sufferer, not only physically but mentally. He quoted Dr. James Mackenzie as saying that a mass of the degenerative changes of the heart were due to auto-intoxication. Dr. Mackenzie had sent him a patient upon whom he operated with the greatest benefit to the cardiac condition as well as to the patient's general well-being.

Dr. ROSWELL PARK, of Buffalo, read a paper on

The Relation of the Ductless Glands to the Work of the Surgeon,

in which he referred to the fact that the internal secretions, or hormones, exercised an apparent controlling influence on many of the organs and functions —and this not only on the ordinary body functions but on the nutrition and regulation of individual organs and their particular activities, even to the extent of becoming responsible for the development of certain mental traits or personal characteristics which might make or mar the individual. He pointed out that even to-day there was much to learn concerning the functions of the thyroid. It seemed to have an influence on the formation of the blood. Its most important work appeared to be elaboration of iodothyrin. Certainly iodine was its most important constituent, and the thyroid was richer in it than any other organ. The parathyroids had only within late years received proper consideration, but in that short time had attained an importance in pathology in inverse ratio to their size. It was now generally believed that nearly all cases of tetany in man were due to defective thyroid function. The thymus seemed to have much to do with the development of the entire bony system; when its activity was reduced ossification was much interfered with and proceeded irregularly and from scattered points; sometimes it failed utterly, as when the first pair of ribs failed to ossify and the other ribs were left weak and subject to early deformity. We could scarcely do more than transplant the parathyroids. The thymus we might have to extirpate or transplant. Transplantation of adrenals had met with questionable success. Removal of the genital glands was rarely demanded for the conditions under present consideration.

Dr. CHARLES H. MAYO, of Rochester, Minnesota, read a paper on

Goitre.

He reviewed the various methods of treating goitres. Regarding exophthalmic goitre, while the disease was amenable to surgical treatment by the removal of a large part of the hypersecreting gland, this procedure must not be considered emergency surgery. During exacerbations all cases should be considered medical. Surgery was indicated during the upward wave of improvement.

Several other papers of value were read. The following officers were elected:—President, Dr. John B. Murphy, Chicago; Vice-President, Dr. George E. Armstrong, Montreal; secretary, Dr. Franklin H. Martin, Chicago; treasurer, Dr. Allen B. Kanavel, Chicago. It has been decided to hold the next meeting of the Congress in London during the fourth week in July, 1914.

Crown 8vo, 1s. net.

"Messrs. Romer & Creasy strip this branch of practice of the cloud of mystery and miracle which has been thrown around it by interested people and well meaning, but ignorant supporters. They effectually disprove the foolish charge that the medical profession has wilfully ignored the subject, and they have dealt with it in an unprejudiced spirit. *Moreover, they bear witness to the fact that the profession* keeps an open mind as to everything connected with the treatment of disease and the relief of pain and physical disability, and is willing to learn from any source anything that may seem likely to be useful for these purposes."—BRITISH MEDICAL JOURNAL.

James Nisbet & Co., Limited, 22, Berners-street, W.

TO ADVERTISERS.

The Manager begs to intimate that in order to meet, to some extent, the demand made by Advertisers for "position" pages—in which respect THE LANCET *will still continue to be deficient as compared with most weekly Journals—the position occupied by this and the following page has been created, and will be known as "Preceding Leader."*

Heavy types or heavy blocks will not be eligible for this position, nor can any border rules be used.

The price will be £12 net per page and pro rata, with a minimum space of one-eighth of a column (=1⅛ in., 15/-), and proceeding by one-eighths (the usual two columns to a page), and consequently there will not be any serial discount.

It will not be practicable to accept any conditions calling for space on either page in particular, or for any precise position on the page, and successive weekly insertions cannot be guaranteed.

W. H. BAILEY & SON

ARE

MANUFACTURERS

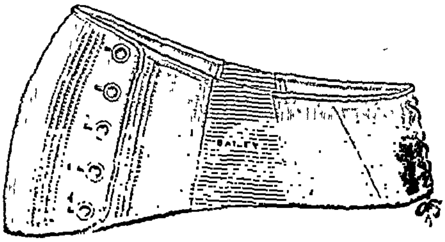
OF ALL KINDS OF

ABDOMINAL BELTS.

BAILEY'S "SIMPLEX" BELT.

BELTS WITH INFLATING PAD FOR MOVABLE KIDNEY BAILEY

These belts are constructed so that they can be applied in the recumbent position, most important in many cases. The adjustment is made by means of the lacing at the back which enables the patient to regulate the pressure according to varying conditions. The belt can be applied or removed by using the side buttons, an easy and expeditious way of adjustment, while a uniform support can be maintained from day to day, or gradually increased if desired.



☞ **IMPORTANT NOTICE.**

MESSRS. W. H. BAILEY & SON are prepared to send (immediately on receipt of letter or telegram) thoroughly Competent Assistants, Male and Female, to attend patients at their Homes, and to take Doctor's instructions. They personally superintend the making and fitting of the Appliance throughout, thus ensuring the best possible results.

38, OXFORD STREET, LONDON - - - For Surgical Instruments and Appliances.
2, RATHBONE PLACE, LONDON - - - For Hospital and Invalid Furniture.

THE LANCET.

LONDON: SATURDAY, JANUARY 17, 1914.

Some Points with Regard to a State Medical Service.

THE difficulties which have arisen in working the panel system under the National Insurance Act may have been magnified, but are none the less real; and the financial conditions which are affecting Approved Societies, owing to the calls upon their resources for sickness benefit, have contributed to bring into some prominence before the general public the question of a State Medical Service. Whether the public has been aroused to any great degree of interest or no, does not alter the fact that we have here a question which affects it no less closely than it does the medical profession. Frequent opportunities have been afforded recently to read observations upon the subject in the lay press, and we may refer here to a temperate and clearly written article which has appeared in the *Morning Post* as indicating the points with which the public must concern itself, if any change in present conditions should come within the scope of practical politics. At the present time there appears to be some misunderstanding of the subject on the part of the public, or the institution of a State Medical Service would hardly have been put forward at meetings of the managers of certain Friendly Societies, with the suggestion that in some manner there would follow upon this drastic revolution of existing procedures a diminution of expenditure upon sickness benefit. This might indeed be brought about by placing all medical treatment in the hands of medical officers appointed by the societies, but we do not conceive that the officers of a State Medical Service would occupy any such position. Their responsibility for the welfare of their patients would be enforced by the superior officers of their own service, and their competency would be tested by the efficient performance of their professional duties, and would not be considered proved by economical advice upon pecuniary matters. This we take to be the view also of Sir JOHN COLLIE, who on Monday last at Caxton Hall argued in favour of a State Medical Service as a substitute for the panel system. In all the circumstances it is not surprising that at the recent conference of Friendly Societies a proposal that there should be a State Medical Service was rejected by a substantial majority.

The establishment of such a service would affect a very much wider public, and one more likely to be critical of the possible medical advantages than those responsible for Friendly Society finance. The members of the societies at present, in contradistinction to the managers of the societies, seem to be well contented, as a rule, with the medical service provided under the National Insurance Act; they do not find fault with the increased expenditure on sickness benefit as long as they are its recipients, and they are also willing to avail themselves of that which the medical profession unanimously declared they ought to have—namely, the free choice of doctor. It is true that this freedom of choice only exists to a limited extent, and it is true also that in some localities it is being threatened, as our Special Commissioner has shown in more than one of the articles in which for the past year he has been reviewing the working of the Acts; but in districts where most of the medical practitioners are on the panel it does exist in a substantial degree. In London, where the number of medical men on the panel is relatively small, and was at one time smaller still, the desire of the working man to choose his medical man for himself is proved by the accumulation of a fund in respect of unallotted patients so large that its bulk has created a difficulty in disposing of it, a difficulty which we cannot help thinking has been much exaggerated. While, then, the public and the medical profession are largely at one, as far as the working of the existing National Insurance Act is concerned, in maintaining the principle of permitting to all sick persons the right to choose their medical attendants, it will be necessary for those who advocate the establishment of a State Medical Service to show how under any scheme of the sort a similar discretion could be given to a far greater public. The development of national health insurance which many expect, and which some consider inevitable, is the extension of medical benefit to the dependents of those now insured. We have seen it estimated that this would bring under the State medical treatment provided by insurance about 40 million out of 45 million inhabitants of Great Britain, and without doubt the numbers would be so large that a scheme of medical service to meet their wants would be almost equivalent to a State Medical Service. But why should these women, on behalf of themselves and of their children, be less tenacious of the right of free choice than their husbands are already? In fact, we should say they would be much more so, and that men being in many conditions of life accustomed to be attended by, and to obey, the particular medical officer appointed for them are familiar in a way which women are not with the principles of regimented service. As matters now stand freedom of choice is enjoyed in different degrees by the whole population. It is exercised most absolutely by the rich, who can go wherever they like in order to consult whomsoever they like; and in great degree by those many others who are, however, restrained by pecuniary considerations from exercising their selection except in their immediate neighbourhood. In less degree still it is enjoyed by those who unless they choose to pay twice over, as insured persons and as private patients, have to consult medical men on the panel of their district, revising their choice at stated periods only. The inhabitants of any district can, however, do for themselves to some extent that which under a State Medical Service would be out of their power. They can by giving general proof of their confidence retain the services of a medical attendant whom they esteem.

A man who has built up and is increasing his practice with marked success is not likely to leave it readily. But under a State Medical Service a medical officer enjoying a fixed salary for the performance of a stated amount of service, would from time to time earn promotion and be anxious to obtain the emoluments of a new and better post. He might be deservedly esteemed by his patients, but his success in treating them would, if anything, conduce to shorten his stay among them, and his removal to a superior position elsewhere would lead to the appointment of another officer, selected, no doubt, with some care for their benefit, but selected entirely by others. The exercise of free choice of a medical adviser is valued in different degrees by different individuals and by different classes, but we can hardly conceive that the large body of those now affected by the Insurance Act who before were not members of Friendly Societies, or who as members conditionally exercised that right, will acquiesce without protest in any attempt to deprive them of it. Moreover, it may be pointed out that members of the legislature are as free to select their medical advisers as they are to select their legal or spiritual advisers, and that they would find it difficult to justify the application to others of a compulsion which they would resent if applied to themselves. The free choice of a doctor is the matter upon which everything turns. That a State Medical Service might offer an alluring prospect to many young men entering the medical profession cannot be denied. The prospect of the possible institution of such a service is a matter of grave importance to the profession and to the public, and its discussion from every point of view is desirable. For this reason we have dwelt upon what we conceive to be certain important practical points; the acceptance or rejection of any innovation by the public when expressed through the ballot-box will probably be influenced by considering the same points. Some form of State Medical Service may arrive, but the difficulties ahead are solid.

Radium and Cancer.

PERIODICALLY the influence of radium over cancer comes under public attention in some form or another through the agency of the lay press, as well as in the columns of medical journals, and the reasons for the enormous attraction of the subject for laymen are clear. On the one hand, we have a fatal disease with such a prevalence that a large proportion of the population have first-hand knowledge of its ravages while in some directions that prevalency seems to be increasing. On the other is a newly discovered element having remarkably fascinating properties, not the least of which is that of inhibiting the growth and development of living cells. About the working of radium we know a good deal. Abnormal cells are more susceptible to its influence than normal ones, so that what may be destructive to the one class is no more than a stimulant to the other. These are the principles which form the basis of the radium treatment of cancer, and they have been known to radiologists for some time past. Take the instance of a small superficial epithelioma; there are now numerous cases of such being cured by a few properly adjusted applications of radium, and there has been no recurrence after some years in cases where but one application was made. This much may be definitely stated, but we are on less safe ground if we say further that all such cases may be cured by the same means. Some carcinomatous conditions arising on a moist mucous membrane, as that of the mouth and tongue, have so far given very poor results from radium or X ray treatment. Furthermore, it may be assumed that the action of radium and the X rays is almost, if not entirely, local, and it is only the malignant cells receiving efficient radiation that are destroyed. The successful treatment of a malignant tumour requires a sufficiency of radium so disposed as to irradiate effectively all the cells of the growth, particularly the advancing margin; it is necessary also that metastasis should not have commenced, for at no stage will radium or the X rays give us control over this unfortunate property of most malignant neoplasms.

Now everything about radium in connexion with the treatment of cancer, that we can as yet be reasonably sure of, has been known to radiologists for a considerable time, and in view of the wide publicity that is suddenly being given to the subject it is inevitable that medical men should ask whether the facts have been multiplied, or whether any new principles have been discovered. The answer is, we think, in the negative, and we therefore find it regrettable that medical men should encourage the publication of a contrary view in the lay press in the absence of any advances that have stood an adequate test of time. No one but a medical man, or a man with considerable knowledge of physics, can properly assess the value of the statements which have recently been made public, and the tendency of the layman has been, we fear, to read into these communications that which he wishes to believe. In many instances grievous disappointment and serious financial embarrassment have been needlessly added to the sufferings of the victims of malignant disease by the publication of ill-understood medical evidence, and deeply interested as we are in the splendid work now being done by radiologists and surgeons with the new machinery at their disposal, we should much deplore this happening in connexion with such work. The crucial question is, How many cases of undoubted and inoperable malignant disease have been completely relieved by radium treatment, and have remained apparently cured sufficiently long to give reasonable hopes of permanent relief? The number must be small, we think, and the permanent relief probably only occurs where the circumstances are unusually favourable. Up to the present radium has brought us little, if any, nearer to the discovery of a definite *cure* for malignant disease, and we feel that our science is not benefited by allowing enthusiasm to outrun discretion. At the same time, we are glad to be able to record considerable advances in practical radium therapy. With larger supplies of radium, and greater experience in applying it where it can do the most good, an increasing number of cases are being relieved and remaining well for a longer time. Far more progress would have been made if all malignant growths of any given variety reacted to radium in a similar manner. But cases apparently alike may give opposite results to the same treatment, and though this may be overcome by improved technique the difficulty is a serious one. It serves to show as much as anything else how very imperfect is our knowledge of this mysterious disease. And could there be a better reason why workers in a promising field should be guarded in their public utterances? We want, before anything is said in public that may lead to bitter disappointment, far more clinical records than we yet possess. The results of cases must be collated and methods must be compared, for which time is required. This we understand to be the feeling also of the Radium Institute, where wards will shortly be opened in extended premises, and where the best of additional opportunities for observation will be afforded.

Regarding the results reported from the cancer research department of the Middlesex Hospital, no stress should be laid upon Dr. LAZARUS-BARLOW'S recent statement. It is that of a pathologist having no responsibility for the treatment of any patients, the figures given are incorrect, and the statement has been repudiated by the surgical staff of the Middlesex Hospital in the columns of the *Times*. With an adequate supply of radium and a series of cases accessible and susceptible to its action, good results are easy to understand, although highly creditable to those who carry out the treatment. But the time has not come for any public announcement, however guarded, pointing to radium as a *cure* for cancer, while any statement of results obtained at a hospital should clearly come from the medical staff who carry out the treatment and watch the results. The rarity of radium limits the number of cases, and for a time all public utterance that is not very carefully worded may be harmful. The present price of radium is probably artificially inflated, but we must remember that the conditions are unusual, and, as anyone who has had much experience of metallurgical chemistry will understand, the isolation of a grain of precious metal from two or three tons of ore is of necessity a prolonged, expensive, and tedious operation. For example, it will require a method of separation very different from that in use at present to enable radium to be sold for a few shillings per milligramme, as has been suggested by Dr. LAZARUS-BARLOW. Also, when we consider that manufacturers can dispose of all they can make for months in advance, and the absence of any reason why the law of supply and demand should not apply in this as in any other commodity, it is difficult to see how the present price can be materially altered until the sources of supply have been extended, and methods of extraction greatly simplified and accelerated. It is noteworthy that an English firm was prepared to supply pure radium bromide at less than £15 per milligramme to some London hospitals. The offer was not accepted and the whole amount, including the output for several months ahead, has been disposed of to Germany at the current rate of about £20 per milligramme. Already we are promised more extensive supplies from Cornwall and simpler methods of extraction are said to have been discovered. If these prospects materialise the outlook for a larger and cheaper supply becomes very bright. In the meantime, we should not allow our enthusiasm for radium to make us forget what we owe to the X rays. In the treatment of accessible growths it is doubtful if radium has any advantage over the X rays properly applied; indeed, it is a question if the X ray tube has yet been used to its full advantage for the treatment of malignant disease. We appear to be on the eve of some radical improvements in the construction of X ray tubes, and if these give us the complete control over the quantity and quality of the radiation that is promised we may confidently look for important advances in radio-therapeutics.

FOREIGN UNIVERSITY INTELLIGENCE.—*Baltimore (Johns Hopkins University):* An arrangement has been made with the University of Breslau for a temporary exchange of teachers, Dr. Felix Landois coming for a semester as assistant to one of the professors (Dr. Halsted), while Dr. Geo. Heuer, who holds that position, goes to Breslau to fill a similar post.—*Basle:* Dr. Eugen Bernoulli has been recognised as *privat docent* of Pharmacology.—*Berlin:* Dr. L. Lesser, professor of dermatology, has been appointed Professor in the Kaiser Wilhelm Post-Graduate Academy; Dr. George Arndt, *privat-docent* of Dermatology, has been granted the title of Professor.—*Breslau:* Dr. Karl Ludloff, surgeon to the orthopædic department of the Surgical Clinic, has been promoted to an Honorary Professorship; Dr. Julius Schmidt, *privat-docent* of medicine, has been granted the title of Professor.—*Budapest:* Dr. Hari, *privat-docent* of medical chemistry, has been appointed Extraordinary Professor.—*Buenos Aires:* Dr. O. Bonorino Udaondo has been appointed Extraordinary Professor of Semeiology.—*Copenhagen:* Dr. V. Schaldemose, Extraordinary Professor of Surgery, has been promoted to Ordinary Professor.—*Florence:* Dr. Francesco Casagli has been recognised as *privat-docent* of Surgical Pathology.

Annotations.

"Ne quid nimis."

THE PROTECTION OF PRECIOUS POSSESSIONS AGAINST FIRE.

ONE by one some of our most interesting national possessions are being lost by fire, and unless measures are taken for the prevention or suppression of fire we may count on losing more. During the past year or two the destruction of several noble historic buildings by fire, together with their contained treasures, has led to a widespread feeling of dismay, and yet no serious or practical attempts appear to be made to prevent these recurring disasters. Every time it is the same story—"there was no water-supply," or "the local fire-engine was not powerful enough to extinguish the flames," or "the only available water-supply was a small pond, which was soon exhausted." Last week the beautiful mansion known as Great Barton Hall, near Bury St. Edmunds, was destroyed by fire early in the morning, and the newspapers have recorded that "the guests (a large house party was being entertained) lent valuable aid in saving famous pictures; but as there was no water-supply the building was burnt out." We commented exactly ten years ago upon the apparent indifference to the results which may follow outbreaks of fire in our historic homes. The occasion then was the destruction by fire of Hanley Castle in Worcestershire, the owner of which, Sir Edmund Lechmere, had lost also by fire a few years previously the ancient mansion "Severn End." This last house, which was one of the oldest in the kingdom, not only contained an interesting museum, but also what we believe was extremely rare, an ancient laboratory, where no doubt bygone members of the distinguished family pondered on alchemical problems, the foundations of which modern research seems to be doing something to rehabilitate. We then asked whether anything could be done to stop this destruction of priceless possessions. We also expressed doubt whether the custodians of country mansions were equal to the task allotted them. We again urge on all placed in a responsible position as owners or guardians of such properties to see that the custodians have both the mental and bodily qualifications as well as goodwill for their important charge. We recommend this matter also to the earnest attention of the British Fire Prevention Committee, which is doing good service by suggesting measures for the prevention of loss of life and property by fire. They would earn the nation's deepest gratitude if they would take up this question of the inadequacy of preventive measures which nearly always proves to exist when our great historic buildings are destroyed by fire. Last week they did well to call attention to the unsatisfactory character of certain portable chemical fire extinguishers. The committee possess records of seven fatalities from certain of these extinguishers bursting, and they pointed out that there is at present an unfortunate tendency to put various types of "cheap-jack" appliances on the market which are not only unreliable but dangerous. We entirely agree with the committee, that the method frequently adopted for selling such wares in our country towns and villages, with the aid of faked demonstration tests, calls for a very decided warning.

THE TUBERCULOSIS CAMPAIGN IN RELATION TO THE EVOLUTION OF SANITARY SCIENCE.

IF the results of the tuberculosis campaign, which has now been initiated in all civilised countries, were limited to the great improvement that is taking place everywhere in relation to the incidence and fatality of that disease alone, the campaign would have amply justified itself. But every specialised advance in science paves the way for a general improvement, and that this is particularly so in this case is made clear in an interesting article by Dr. Hermann M. Biggs and Dr. Charles F. Bolduan,[1] who are drawing their material for argument from American sources. The authors point out that the close student of public health in the United States has for some time seen in the development of this campaign the genesis of a new conception of public health administration and the consequent introduction of new methods of work. Twenty-five years ago, when this campaign was begun in America, the efforts of public health officials were centred in such general problems as pure water supplies and sewage disposal, removal of rubbish, abolition of nuisances, and efforts to abate the spread of the more readily communicable diseases, with some attempt at quarantine and disinfection. The first step towards an enlarged scope was the natural consequence of Koch's discovery of the tubercle bacillus, which pointed the way towards the discovery of the nature of infections and a more accurate knowledge of transmission of infectious disease. With this knowledge coordinated action became possible, and three main lines of effort emerged, tending respectively to the discovery of cases and the study of the problems involved (notification and registration, home visitation, provision of diagnostic facilities, and educational work); special care of the cases found (by institutional and social means; and the securing of the greatest efficiency of the medical and social preventive measures through organisation and coördination of the various agencies. Much the same history holds good, of course, when told in connexion with any of the great civilised states of the world. And in the same way as the extent and manner of distribution of tuberculosis have grown clear those of other diseases are becoming known; the underlying causes of infection are being discovered and dealt with at the source and along their lines of distribution. The recognition of the fact that tuberculosis is not a mere bacterial invasion but rather a symptom of social pathology is now finding its extension towards other diseases, we may give as an example the acknowledgment of venereal disease as a social and not merely a medical problem. The laboratory assistance in diagnosis offered for many years in connexion with tuberculosis is now extended to many other diseases, and will in the near future extend to many more. The importance of helping the diseased sufferer not merely for his own sake but as a measure of self-protection for the community will be more rapidly acknowledged and acted upon by the establishment of various kinds of institutions necessary for isolation, support, domiciliary supervision, and what not. Medical inspection of school children is taking on a vastly wider extension, not simply confining itself to checking the spread of infectious disease but aiming at the building up of a physically, mentally, and morally more perfect race. During the last 50 years the duration of life in many of the large cities of the world has been extended 25 per cent., and it is patent to everyone that the man of to-day at 60 years of age is quite frequently in the prime of life. Perhaps the modern mental attitude has to do with this. We have ceased to think that our life's work is approaching its term at 60, and so when that age comes we do not notice any great difference between that age and 50, or even 45. Not to recognise the disabilities of age is one important factor in warding them off. We do not mean that a man should ignore limitations to his powers which objective evidence demonstrates to be present, but we are certain that he should not encourage their advent by expecting them as due at a certain period of life.

---

[1] The Tuberculosis Campaign: its Influence on the Methods of Public Health Work Generally. By Hermann M. Biggs, M.D., and Charles F. Bolduan, M.D. Department of Health of the City of New York Reprint Series, No. 8, August, 1913.

TROPICAL DISEASE RESEARCH.

Mr. Austen Chamberlain, M.P., is to be heartily congratulated upon having collected £71,000, to which £1000 interest must be added, making in all £72,000, for the fund which he initiated on behalf of the London School of Tropical Medicine. Although this sum falls short by £28,000 of the amount originally asked for, it is a substantial and generous response to the appeal, and as it will provide for the immediate necessities of the school the closing of the fund has naturally followed. From a circular letter to the subscribers we learn that the new buildings have cost £15,000, and that very efficient labor
modation for stude
original research .
being the amount devised by the late Lord Wandsworth to be used at the discretion of Sir William Bennett, who placed it at the disposal of the school, and £6000 have been invested, the income of which will provide beds for tropical cases. The remainder, a little more than £40,000, has been invested in trustee securities, and the income thereof has been made available for the general purposes of the school. It will be remembered that the appeal for £100,000 was made with the object of providing a modest but adequate endowment fund; to make necessary additions to the laboratories and buildings; to provide for the active prosecution of research; and to furnish a certain number of beds for civilians who could not afford to procure for themselves the special medical and surgical treatment required by patients suffering from tropical diseases. These objects have now been secured, but although the fund has been closed further donations are necessary if the remarkable results which have already attended research in tropical medicine are to be continued. And it is not only in the promotion of health that the achievements in this department of medicine have been so remarkable, but also in commerce and all that concerns the expansion of our Empire. The object should therefore appeal to every member of the community, and especially to commercial men whose interests are widely affected by our knowledge of tropical diseases. The possibility of the introduction of yellow fever into India in consequence of the opening of the Panama Canal is one of the latest problems with which tropical disease research is having to deal, and this is only one of the many that may occur in the future. It is, therefore, of imperative importance that such research should not be hampered by want of money. We confidently hope that, although Mr. Chamberlain's fund on behalf of the London School of Tropical Medicine has been closed, further donations will be forthcoming, and that there will be no check to the progressive advance in our knowledge of those diseases which not only affect the health of the people but also the commercial stability of the Empire.

A SPECIAL DIPLOMA FOR SCHOOL DOCTORS.

THE December issue of the *Journal of State Medicine* contains an article by Mr. J. R. R. Trist on the Medical Inspection of School Children and Medical Education, in which he draws attention to the practice of education authorities in demanding a public health diploma from candidates for appointments in connexion with school inspection. The practice follows logically on the general recognition of school hygiene as a department of public health, but Mr. Trist considers that "the time has come when medical educational authorities may well draw up a course of study and prescribe an examination for a 'diploma in school medicine,' which shall include a part of the curriculum for the D.P.H., and also be such as to give evidence of a knowledge of disease in children." It is certainly desirable that local authorities should pay more regard to a knowledge of children's diseases in candidates for school medical appointments, and if any such examination is instituted as Mr. Trist suggests it should include a section devoted to the medical-social side of the subject. The work of care committees and the coöperation of doctors with many and varied social organisations which have to do with child welfare form an increasingly important part of a school medical department. To lack the power of coöperation and the knowledge of organisation necessary for this work is to fail partially in getting good results from medical inspection. Mr. Trist mentions as special departments of knowledge in which a medical inspector should be expert, or at least have a thoroughly good understanding, dermatology, ophthalmology, otology, neurology, and orthopædics. While agreeing in the main with this statement, it is necessary to add that this knowledge must be tested and brought into the perspective of school inspection by attendance at a school clinic. The ordinary hospital out-patient clinic gives quite a false impression of the relative importance, from the school point of view, of various ailments and "defects." There is also another department of knowledge in which the school doctor should be well equipped, and that concerns the feeding of children. Probably in no other department of practice is the medical profession so badly equipped as in the department of dietetics. Laboratory physiology is of very little practical use, and the grave contradictions found between different "authorities" on diet point unmistakably to the conclusion that our present knowledge is of very little worth. And among large classes of the population the question of clothing is of hardly less importance than that of feeding. To suggest that the school doctor should not only be expert in various special departments, but also the possessor of social tact and be something of a cook and a tailor, is in truth only to suggest that he should enter fully into the spirit of his duties. The school doctor cannot rest content until there is a permanent improvement in the health of the child population of the country, and everything which appertains to that is within his province. And to help toward the better equipment of the school doctor it seems probable that something on the lines of Mr. Trist's suggestion will have to be considered, but to be valuable the examination should cover everything within the sphere of influence of the medical inspector of schools.

ARTERIO-VENOUS ANEURYSM OF THE SUPERFICIAL FEMORAL VESSELS.

THE discovery at necropsy of lesions which had given little or no trouble during life has proved a corrective to the spirit of gloomy prognosis which is apt to dominate those who, as in the case of hospital physicians and surgeons, spend a large part of their lives in the contemplation of mortal disease. Malignant growths that have been known to exist without giving rise to trouble for many years, in patients who eventually die from something else, impress upon the mind of the clinician the same golden lesson that there is no such thing as a hopeless outlook. In the *Journal of the American Medical Association* for Dec. 13th of last year there is an account of a case of arterio-venous aneurysm, the most noteworthy features of which were the extent of the lesions, their long duration, and the unimportance of the symptoms to which they gave rise. The patient, a medical man aged 63, was admitted to St. Luke's Hospital, New York, with symptoms of cardiac breakdown which proved fatal in a week. In addition to the symptoms and signs proper to the cardiac disease there was a tumour in the left groin, of the size of a hen's egg, exhibiting expansive pulsation, over which a continuous bruit with a systolic emphasis could be heard. It was said that 18 years previously he had been wounded in the thigh by a small-bore rifle bullet, but that since that date he had travelled much in South America and spent a good deal of his time in the saddle. As Dr. A. B. Eisenberg, who reports the case, remarks, this strenuous life could not have been borne had the patient suffered much from the aneurysm. At the necropsy it was found that the bullet must have perforated the superficial femoral artery and vein about two and a half inches distal to the origin of the profunda femoris artery; both vessels had been completely traversed, and the points of entrance and exit lay exactly opposite each other. The adjacent portions of artery and vein had been incorporated with each other, the corresponding perforations persisting in the form of a communication about a third of an inch in diameter. The other hole in the artery established a channel between the vessel and a small, thick-walled aneurysmal sac. There was probably a corresponding venous sac; but this part of the specimen was damaged in the process of removal, and could not be accurately observed. Both artery and vein were thickened and dilated for a short distance below the communication, and markedly so above it; constricted by their passage beneath Poupart's ligament, they were dilated again above it, and so much contorted that this portion of both vessels was more than double the normal length. Just above Poupart's ligament the vein dilated suddenly to form a thin-walled sac, nearly three inches in length, and about two and a half inches in diameter. In spite of these extensive lesions which, as Dr. Eisenberg expresses it, crowded the pelvis, there had been no urinary or rectal symptoms, though both ureters were moderately dilated.

NEUROTIC RAILWAY WORKERS.

THE report of Major Pringle, the Board of Trade inspector, on the collision which occurred at Waterloo Junction Station on Oct. 25th, 1913, and was attended with serious loss of life, attributes the accident to faulty judgment and lack of caution on the part of one of the signalmen. This finding, taken in conjunction with the results of inquiry in some other accidents of recent date, will strengthen the view that in the interest of public safety there is need of a somewhat more complete and more stringent medical supervision of railway employees than exists at present. Defects of colour perception are recognised as a disqualification for the railway service, and tests, if not wholly satisfactory ones, are regularly applied for their detection; but, as this accident shows, a defect in inhibitory power or a weakness of attention may be a disability quite as serious in its consequences as the failure to distinguish the sensations of red and green. It is, doubtless, quite true that the qualities found wanting in the Waterloo signalman are not susceptible of very exact measurement even by the most elaborate methods of psychological examination, but these methods might at all events furnish the data for a rough estimate of the nervous aptitudes of a given individual, from which his fitness or unfitness for certain sorts of work could be inferred with some degree of probability. And investigation by such methods might also throw light on the influence which the conditions of his occupation exercise on the railway worker's efficiency. The practical importance that may possibly attach to this latter point is shown by the reference in the inspector's report to the suggestion, which he seems to admit in a qualified way, that the sameness and routine character of the work in a busy signal box tend to deaden the capacity for thoughtfulness, and may thus help to bring about such rash and hasty action as was responsible for the Waterloo accident.

THE FUNCTIONS OF THE NOSE.

IT is generally agreed that the functions of the nose are connected with the sense of smell, respiration, taste, and phonation; but this view has been challenged by Dr. Owen F. Paget, medical officer of health of Fremantle, Western Australia, who wishes to prove that the most important function of the nose is to filter the inspired air, and that all other uses to which it may be put are merely subsidiary to this. He holds that nearly every healthy man has lost the power to breathe through the nose, and he explains this by the fact that in inspiration the sides of the nose collapse and the passage is blocked, and this occurs quite apart from any abnormality such as deviation of the septum. This collapse he ascribes to a loss of power of the nasal muscles from disuse, for he believes that all the muscles of the nose except the depressor alæ nasi act as dilators of the nostril. If by one means or another respiration even when hurried could be completely nasal, he believes that pneumokoniosis and allied disorders would be abolished, and that there would be an enormous diminution in pulmonary tuberculosis, pneumonia, and influenza.

We regret that the exigencies of space prevent our presenting Dr. Paget's views in full, but we have given above a brief summary of them. His suggestion is interesting, and will no doubt receive attention.

THE IMPERIAL BACTERIOLOGICAL LABORATORY OF INDIA.

MANY of our readers are probably acquainted with the important work carried on by the Pasteur Institute at Kasauli, in the Punjab; but perhaps it is not generally known that another centre of research work in the Indian Hills is in active operation at Muktesar, near Naini Tal, in the United Provinces. This was originally started by Dr. Alfred Lingard in 1893. In 1908 Dr. Lingard retired, and was succeeded by Major J. D. E. Holmes, C.I.E., M.R.C.V.S., who has a staff of an assistant bacteriologist, a physiological chemist, three European laboratory assistants, and numerous native assistants and veterinary inspectors. Muktesar stands on top of a hill, at an elevation of about 7500 feet, the estate comprising 7000 acres, half of which is forest. Besides the main laboratory buildings there are three separate laboratories for anthrax, *charbon symptomatique*, and mallein preparation, together with a sterilising house, cold storage, power house, stables, cattle sheds, and dog kennels, &c. The duties of the Imperial bacteriologist, when first appointed in 1890, were thus defined: "To investigate diseases of domesticated animals in all provinces of India, and to ascertain as far as possible, by biological research both in the laboratory and when necessary at the place of outbreak, the means for preventing and curing such diseases." Year by year investigations have been carried out on surra as affecting horses, camels, and dogs; rinderpest, affecting cattle and buffaloes, epizoötic lymphangitis, dourine, anthrax, hæmorrhagic septicæmia, and *bursati*. The results have been published, either separately by the Indian Government, or as contributions to the *Journal of Tropical Veterinary Science*, or elsewhere. The economic importance of such a research institute is becoming increasingly recognised. The study of the diseases, until recently obscure, of horses and cattle, due to trypanosomes (surra and dourine), epizoötic lymphangitis (first diagnosed and described in India by Dr. Lingard), rinderpest, piroplasmosis, &c., has been carried out thoroughly with all the appliances of modern scientific research. No doubt a considerable sum of money has been expended on the erection and maintenance of this institute, but the value of the results is already acknowledged, and year by year will become more appreciated. In India rinderpest is the most prevalent and destructive disease of stock; in this, as in other epizoötics, the operations of the Government Veterinary Department are directed to the suppression of the outbreaks as they occur, the treatment and protection of individuals being of less consideration, and total eradication not being even attempted, as it is practically out of the question. Next to rinderpest hæmorrhagic septicæmia accounts for the largest losses among cattle. For glanders, surra, epizootic lymphangitis, and dourine there exist legislative measures of control. For rinderpest the use of serum is accepted without opposition in most parts of the country on account of the great benefits which have resulted during the last ten years, and which are freely acknowledged. A successful method of curing surra was discovered at the laboratory in 1908; atoxyl and arsenic are used, and 75 per cent. of the horses and mules treated have recovered. Dogs have been cured by salvarsan. The above is a very slight sketch of the work carried out by the Muktesar laboratory, the existence of which is a proof of the appreciation of modern scientific methods by the Government of India. The great value of its prophylactic work is probably at present understood and appreciated by comparatively few, but the time will come when it will be fully acknowledged. The practical difficulties in establishing laboratories and carrying through *delicate bacteriological work and microscopic* research in the Himalayas must have been considerable, and great credit is due to Dr. Lingard and his successors for the valuable results that have been obtained.

DISEASES OF NATIVES IN NEW GUINEA.

WHY do uncivilised nations die out? This question is being answered in the German colonies by careful statistical investigations, of which the latest to come under our notice was made by Dr. Karl Kopp in New Pomerania,[1] German New Guinea. He found the people well fed, the children in good condition, but the adults spare and the aged thin. There were plenty of children, and he gives a table showing the proportions which children under 15 bear to the general population: in New Pomerania, 614 out of 1000, but the men seem to emigrate in search of work and would not be enumerated, so the child ratio is too high; in Austria, 563; Germany, 534; England, 529; and France, 353. There are more men (who are generally idle) than women (who do nearly all the work). The most frequent causes of mortality and of disabling constitutional weakness are first and chiefly "the scourge of the South Seas"—ankylostomiasis; 62 per cent. of children in the schools were found infected. The only children who harboured no intestinal parasites all wore boots, the infected all went barefoot. He says with great truth that many a planter who groans over the weakness and idleness of his coolies would much better spend his time contriving for them a safe water-supply and decent latrines so they could do their work. Malaria and filariasis, mosquito-borne diseases, come next. They each do much harm by setting up an anæmia which depraves the man's working power and makes him an easy victim to the next infection that comes along. Tuberculosis is not endemic yet; it has been communicated by strangers, and hence it is the men, who more often meet them, who are most infected; women and children escape more lightly, and the disease has barely reached the natives who live far in the wilds. It is observed that the disease spreads more rapidly in a village well protected from the wind and with its houses therefore less well ventilated. This is interesting in connexion with what Dr. William Gordon has found in Devonshire, where villages appeared to be susceptible in proportion to their exposure to the south-west wind.[2] Cases of yaws also are frequent in New Guinea, and a gingivitis which may be scurvy. Syphilis also has been imported; as Dr. Kopp remarks, it is a Greek gift from civilised visitors; also dysentery occurs frequently. The chief of their unhealthy customs are smoking, which is continual and has been seen to be practised even by sucklings, chewing betel nut, and careless, unregulated depositing of fæces. His hope for the future is with the Government labourers and recruits, who shall find so good sanitary arrangements in barracks that they will be unable to live without them in their homes on their return.

EARLY DAYS OF CHLOROFORM.

THE death, at the age of 83, of a niece of Sir James Simpson, which occurred last week at Streatham, brings to mind the early days of anæsthetics. We have grown so accustomed to their use, and alterations and advances in the practice of anæsthesia follow so rapidly one upon another, that we easily lose sight of the fact that it is really only a short time since the first anæsthetics were introduced. Mrs. Agnes Thomson was, so far as we know, the first woman to inhale chloroform, which she did experimentally at Simpson's house in Queen-street, Edinburgh, where he and his assistants were investigating the newly discovered drug. Miss Petrie, as she then was, after witnessing the effects of chloroform on Simpson and some of his assistants, volunteered to try it, and apparently she enjoyed the inhalation, for she repeated it on more than one occasion. No doubt what we now regard as surgical anæsthesia was never attained, and the pleasant sensations she experienced are often paralleled at the present time by those who are subjected only to short periods of administration and to no deep degree of narcosis. Chloroform, we may remind our readers, was no haphazard discovery, but was the direct result of Simpson's desire to find an anæsthetic less irritating than ether, which had been already introduced and was used by Simpson early in 1847. It was in November of the same year that he read his "notice of a new anæsthetic agent as a substitute for ether in surgery and midwifery," in consequence of which chloroform rapidly supplemented ether, until the greater danger of the former drug became apparent. There is an interesting picture of these early chloroform experiments of Simpson, which partook almost of a domestic nature, and of those taking part in them, in Lady Priestley's "Story of a Lifetime." Her husband, the late Sir William Priestley, was one of the many young Edinburgh medical men who were infected with the enthusiasm and joyous spirit of investigation which animated their great teacher.

FATAL HÆMATEMESIS DUE TO ANGIOMA OF THE PORTAL VEIN.

IN the *Berliner Klinische Wochenschrift* for Dec. 1st, 1913, Dr. Hart has reported a case which throws light on the origin of one form of gastric hæmorrhage. His patient was a governess, aged 20, who had previously been well. In March, 1913, an attack of violent hæmatemesis was followed by collapse. After five days, during which the hæmatemesis continued, the patient died. The necropsy showed dilatation of the veins of the œsophagus and the stomach, and a ruptured varicose vein in the latter. The spleen was much enlarged and surrounded by adhesions. There was no sign of a normal portal vein, the place of which was taken by a spongy structure consisting of innumerable minute blood-vessels. This was evidently the point at which obstruction to the circulation of the abdominal veins had induced enlargement of the spleen and dilatation of the gastric veins. As there was not even a fibrous cord in place of the portal vein, this cannot at any time have existed, and the angioma must be regarded as a congenital anomaly. It is astonishing how such a condition could have lasted for 20 years before the congested veins gave way. The liver contained gummata, and at first sight the angioma would seem to be dependent on congenital syphilitic disease of the liver; but Dr. Hart thinks, in view of the patient's history, that the syphilis was acquired, and had nothing to do with the angioma. Of late years a few cases have been recorded in which the portal vein was replaced by cavernous tissue. Sometimes this has been limited to the portal vein; and at other times it has extended to the splenic vein and to the intrahepatic branches of the portal vein. It is practically impossible during life to distinguish this condition from cirrhosis of the liver, Banti's disease, and polycythæmia. The condition may be fatal as a result of late thrombosis of the branches of the portal vein with infarct of the corresponding portions of the intestine, or as a result of hæmorrhage from an œsophageal or gastric vein. The condition does not necessarily affect the liver, and its origin is still in dispute. Some authorities regard the angioma as a sequel to thrombosis of the portal vein, followed by recanalisation and the formation of capillary, collateral blood-vessels. Others consider that an angiomatous tumour has grown from the wall of the portal vein, which has ultimately become obstructed. Others, again, regard the condition as a congenital malformation. It has probably been overlooked more than once at necropsies, and thus the cause of a fatal gastro-intestinal hæmorrhage has not been discovered.

THE POLICE PATIENTS IN METROPOLITAN HOSPITALS.

THE metropolitan police force now numbers 22,000 men, and they form a picked body, for only about 25 per cent. of the candidates are accepted. The last published report of the Chief Surgeon of the Metropolitan Police, that for the year 1912, shows the general health of the force to be good, but reveals also how their arduous duties entail a corresponding sickness rate, whilst the number of police injured in the course of their routine work is very large. For instance, in 1912 3075 policemen were injured in the execution of their duty, over 2500 having been assaulted when making arrests, of whom 329 were placed on the sick list for more than one week. 369 patients during the same year were admitted into general hospitals, 33 into cottage hospitals. and 172 into special hospitals, making a total of 574, 22 of whom died. The figures show that the hospitals of the metropolis minister in an important manner to the health and well-being of the police force over a huge area. We have just received with particular pleasure a communication from the Office of the Commissioner of Police stating that it is proposed to alter the basis on which subscriptions are paid to the metropolitan hospitals from the Police Funds in return for the ministrations rendered to police in-patients. Hitherto certain subscriptions have been paid by Scotland Yard to different hospitals in a completely arbitrary way, so that it might easily happen that one charity, receiving a small subscription, would be affording treatment to 40 or 50 police in-patients during the year, while another receiving a larger subscription, might during the same year shelter only one or two policemen in the wards. Under the new arrangement, which has been made at the instance of Sir Edward Henry, the Commissioner of Police, and with the approval of Mr. McKenna, the Home Secretary, the subscriptions from the Police Funds, while remaining as at present on a voluntary basis, will be approximately equal to a sum of 1 guinea per week on account of every police in-patient admitted to the hospital during the year. Further, from any officer above the rank of inspector who may be received in one of the hospitals an additional contribution will be expected, and the Commissioner of Police invites the management of the various hospitals to communicate with him when such a case arises, so that the suitable provision may be made. We know that this valuable change in the method of dealing with police in-patients in the metropolitan hospitals has long been desired by Sir Edward Henry, as an obvious way of making a more equitable recognition of the services rendered by the hospitals to the police, and we are certain that the new arrangement will be acceptable to the governing boards of the respective institutions concerned. A far larger sum of money will now be paid to the hospitals in recognition of the medical and surgical treatment received by police in-patients, and that sum will go in the different directions where it has been earned. We heartily congratulate Sir Edward Henry on carrying through a valuable piece of administrative reform.

AT the next meeting of the Royal Microscopical Society at 20, Hanover-square, London, W., on Wednesday, Jan. 21st, at 8 o'clock, Professor G. Sims Woodhead will deliver his Presidential address on "The Microscope and Medicine."

SIR JAMES PAGET'S CENTENARY.—In our last issue the vicar of Great Yarmouth announced that the centenary of the birth of Sir James Paget would be commemorated at Yarmouth parish church on Sunday, Jan. 11th. Sir James Paget was born at Yarmouth on Jan. 11th, 1814, and his family was closely connected with the district and its parish church. An impressive service was accordingly held, at which the sermon was preached by the Bishop of Stepney, third son of Sir James Paget. The mayor and corporation of the borough attended, and representatives were present from St. Bartholomew's Hospital, from the University of Cambridge (in which Sir James Paget's brother, Sir George Paget, was professor of medicine), and from various medical societies. After the service the mayor received on behalf of the corporation from the Bishop of Stepney and Mr. Stephen Paget certain pieces of plate and other souvenirs which had been presented to their father by the citizens of his native town.

A JOURNAL OF PHONETICS.—The birth of a new journal devoted to any department of medicine is necessarily one of interest. The journal which is now attracting our attention is termed the *Archiv für Experimentelle und Klinische Phonetik*, and is edited by Professor J. Katzenstein. In this first number Dr. Otto Weis deals with the formation of the vocal—this word should be used in the same way as it would be employed by the singers—and there are several photographs of curves of sounds produced in various ways and in various parts of the vocal apparatus. There is a contribution to the Physiological Study of Phonetics, by [illegible] long, fully illustrated article on [illegible] me of Air in Speaking and Singing, [illegible] and R. du Bois Reymond. The articles of this first number mentioned will give some idea of the scope of the journal, and one feels sorry that there is not a journal devoted to this subject in the English language, though we expect it would be extremely difficult to produce one of equal merit.

THE RATIONAL TREATMENT OF INCIPIENT INSANITY AND THE URGENT NEED FOR LEGISLATION.[1]

BY ROBERT ARMSTRONG-JONES, M.D. LOND., F.R.C.P. LOND.,
RESIDENT PHYSICIAN, LONDON COUNTY COUNCIL ASYLUM, CLAYBURY AND LECTURER ON MENTAL DISEASES TO ST. BARTHOLOMEW'S HOSPITAL; FORMERLY EXAMINER IN MENTAL DISEASES, UNIVERSITY OF LONDON.

THE victims of insanity in its many forms claim the protection and the care of the two sections of which the Medico-Legal Society is constituted. They come under the care of the medical man for their mental and physical condition, and they need the supervision and help of the lawyer for the custody of their property and for the safeguarding of their liberty. In consequence of this dual control the term insanity probably has for members of the society two different meanings. To the medical section insanity is a disease which brings about (sometimes suddenly, but more often gradually) a change in conduct of such a kind that actions or speech indicate a loss of self-control and self-direction. As a result of this change in conduct the community in which the sufferer lives demands for his own safety and that of others that he should be placed under circumstances in which he may best regain his lost balance. To the legal section an insane person is one who has become recognised as such through the filling up and signing of certain forms and schedules in accordance with the provisions of an Act of Parliament, so that insanity in this sense is a transition from one territory or province into another, the line of demarcation being a legal one. The transition takes no notice of the condition necessitating the change, only of the delimiting frontier, which is certification. On one side of this frontier there is one law for him, on the other there is another; and it is the disqualifying condition which accompanies this certification that constitutes the basis of this paper.

The Stigma attaching to Insanity.

One of the chief functions of the Medico-Legal Society is to formulate and discuss schemes of legislation relating to important medical matters, and the insane subject needs legal support because an obloquy, a shame, and a disgrace attach in the public mind, and most unjustifiably, to insanity, to insane persons, and even to the places wherein these are now treated and cared for. Whilst recovering from this terrible disability no convalescent home will receive them, no family welcomes them, and even relatives and friends are suspicious and timid in regard to them. Their own children often shun them, and even when restored to their former health, as I am happy to say is very frequently the case when they come under treatment early, there is a difficulty in reinstating them in their former places owing to the prejudice which exists so widely. It is the duty of those who are acquainted with this sad affliction and who know the sufferers best to help them against the antipathy and to try to alter the public feeling which now prevails against them.

---

[1] Paper read to open a discussion at the Medico-Legal Society, under the chairmanship of Earl Russell, on Nov. 25th, 1913, at which Dr. [illegible] Sidney [illegible] and [illegible] Sir G. [illegible] and to [illegible] tions. [illegible] Dr. Henry Maudsley was present.

Of all disabling illnesses insanity is the most formidable, as it is also the most expensive, and the most difficult to deal with, yet if treated in its early stage it is most successful in results, which fact is of immense importance to the community, both from the point of view of prevention as well as of finance, for which reasons cases of insanity should receive prompt attention at the very outset.

Incipient Cases.

There are in round numbers 140,000 insane persons in England and Wales, and the cry is that these numbers are increasing. In addition to those who are insane there is possibly an equal number on the borderland. Many parents sacrifice themselves in order to give good schooling to their children and to equip their boys and girls for the battle of life, the gates of progress to-day being forced only by those especially prepared for the fray. Yet education has its victims, the physical side of children being often sacrificed to the mental, both parents and teachers forgetting that the secret of successful competition is first of all to have a healthy muscular and nervous system. The "speeding up" which is now universal has to start from below, time is precious and work has to be done at a white heat, and there is urgent need for a reliable physical health, for the neurasthenic class has never been more numerous than it is to-day, and it has become the fashion to run "homes" for all sorts of nervous breakdowns, as the friends of the early insane know already to their cost. If it were only more widely known how incipient insanity may be controlled and quickly relieved there would be a national effort to provide means for treatment and early advice. Yet what is being done to-day to prevent these cases becoming incurable and to keep down the numbers of the certifiable insane? It is but little known how many there are, especially among the poorer classes, who are struggling hard against tremendous odds to keep their ill ones out of the lunatic asylum and out of the workhouse infirmary as well. Few know the efforts made by the deserving poor to fight against a "damnable heredity," and it has been well said that the value of a life should be measured not by success but by effort.

The Legal Position.

The munificent gift of Dr. Henry Maudsley to the London County Council—viz., the Mental Hospital, which is to be called after his name in South London, is destined to be the finest clinic in the world, but before it can be of full use there must be a change in the law of lunacy. So far as England and Wales are concerned there is to-day in lunacy one law for the rich and another for the poor. But even a rich person who is suffering from insanity cannot be looked after upon payment even by his own father, mother, brother, sister, or any relative or friend except at the penalty of a fine, or being summoned in an action for misdemeanour. Further, no person suffering from insanity can be kept or maintained for payment unless that person is certified and registered as a certified lunatic. A person who is restless from loss of sleep and delirious with excitement cannot be looked after in any home or hospital except at the risk of an action being brought against his custodian for maintaining a person who should have been certified. But what does the certificate imply? It carries with it the stigma and the reproach—unjust as they are—of insanity, and once certified the reproach remains, not only in regard to himself, but also to his family and his relations. To my knowledge many men have lost their situations in the service of the Crown, in the employ of public companies, and frequently in private service, owing to the stigma of insanity which certification implies. Many humble persons have been deprived of their livelihoods and have been actually prevented from recovering because they realised the portent of the certificate of insanity.

Causal Factors in Insanity.

Whilst it is customary to blame alcoholic excess for most of occurring insanity, nevertheless insanity is a condition with many antecedents and innumerable causal factors; unhealthy surroundings, the want of fresh air and sunshine, long years of strain and worry, noise, sleeplessness, and bad food are frequent etiological factors, which show that the person afflicted is not to be blamed for his own illness. Insanity is a gradual rather than a rapid change. A case illustrating physical causation is given, if I remember rightly, by Dr. Lewis C. Bruce; another on the mental side by Dr. Helen Boyle. The physical factor is illustrated by a mother who gives birth to a child; her confinement is associated with a slight fissure of the cervix uteri; over this fissure runs a discharge from the uterus which inoculates the wound with streptococcic or staphylococcic infection. After months, possibly years, of continuous infection her health at last gives way and she becomes a complete mental wreck, which proper treatment of the fissure at the start would have prevented.

On the mental side the example is that of a needy home and a poor mother with a large and young family. She stays up at night nursing her sick child in an overcrowded room—often with bad air and worse food, with noise and worry. Later she becomes sleepless, loses her appetite, her general health fails, and she is threatened with a mental breakdown, possibly complicated also with tuberculous infection. She knows she is going down hill, she becomes melancholy, and develops delusions. She feels unable to cope with the calls of home or with the needs of her husband and children; she is no longer able to do the mending, darning, washing, cleaning, and cooking expected of her, and she seeks medical help and advice. She waits for hours at the out-patient department of a general hospital and gets a bottle of medicine, with the advice not to worry, but to go home and rest. She is told she cannot be taken into the hospital because she has no definite organic disease, and she is not eligible for the asylum because she has not been certified. Even if she were, she would have to go into the workhouse first, which she dreads. She fears still more the stigma of the lunatic asylum, which will not only stamp her as an outcast among her family, but will also cast a permanent blemish upon her children.

Cases Needing Special Treatment.

These are the kinds of cases that need special treatment to save them from the stigma of insanity, and there are many more besides. There are those who suffer from the delirium of bodily illness such as may accompany an attack of pneumonia or pleurisy, or some of the acute fevers—more commonly perhaps typhoid and scarlet fever, many who suffer from the temporary delirium of puerperal toxæmia, some who suffer from renal uræmia, and scores of people who have "drunk not wisely but too well."

I have seen many instances of teachers,

governesses, maids, of poor clerks and working men among these cases, who, if they had been able to receive treatment in a general hospital, or some special place intermediate between the hospital and the lunatic asylum, would never have been certified as insane, and would not in consequence be deprived of their livelihood; nor would their relatives and dependents have been further debased by the additional stigma of pauperism. Picture, for instance, a young mother, after her first confinement, finding she has been from three to six weeks in the county asylum as a pauper lunatic—and there are scores of such cases. In her case each successive pregnancy is a nightmare to her, and, in the opinion of some, her own distress will have brought its bad effects upon the children born later. Other cases occur in which persons of a highly strung or nervous temperament have suffered from accident or shock, and as a result have become deliriously restless and excited. Without their knowledge or the consent of their friends they have been certified as insane and removed to the nearest lunatic asylum, and their future careers thereby absolutely destroyed. Many cases suffering from the effects of alcohol have, in consequence of mental symptoms lasting some days, been removed to the Poor-law infirmary; and here, it is satisfactory to know, efforts have been made to save many of them from the reproach of lunacy by detaining them until the mental symptom had passed away, and in some of the larger towns a successful effort has been made to treat these cases in the Poor-law infirmary wards, where nearly 50 per cent. of them have recovered completely within the statutory period of 31 days' detention. By this treatment their future position at least has been protected, and there has also been a saving to the public purse by delayed certification. It is cruel that these rescuable cases and their families and relatives should not get a chance of being saved the reproach of a painful as well as of a permanent stigma. For humanitarian reasons, apart from financial considerations, and for reasons which tend to affect the self-respect and the position of the family, it is right that these persons should have a chance to escape from the censure of being branded with lunacy, if this be possible, and we know that it is. It is hard enough for healthy men to compete with the world, how much more so those who are sensitive and refined, and who through no fault of their own have been compelled to yield in the unequal strife and struggle.

Institutions for Incipient Cases.

As the law now stands the rich man can be placed as a voluntary boarder in a licensed house or a mental hospital if he should feel a mental breakdown impending, and why, if this is satisfactory and possible for the well-to-do, should it be withheld from the poor? The rich patient may also enter a private house to be treated singly, but the poor have to be herded together, and in addition have to pass through the workhouse or Poor-law infirmary and be further censured for their illness as paupers. I do not wish to say anything against the treatment in Poor-law infirmaries. It is as devoted and as able in many of these infirmaries as it is in most of our general voluntary hospitals. But association with Poor-law relief is a stigma.

Although I have stated that the insane rich may enter private houses or homes, these homes are not by any means what they might be. We know there are scores of so-called "retreats" or nursing homes ostensibly for cases of this kind described euphemistically as "nervous" cases, but the cases are looked after often by persons who know little or nothing of the conditions of incipient insanity. I have recently seen a man who spent practically the whole of his savings in residence at a nursing home, in which his mental disorder continued to develop and where much valuable time was lost in "curing his nerves" with galvanism and what was described as the "rest cure."

All who practise in my department of medicine know of these nursing homes, and there is, through the fear of the stigma of insanity, a tendency on the part of the relatives and friends to avoid asylums and to make use of them. A great deal of trouble is also often experienced in dissuading the friends from placing mental cases in them. There are many doctors in practice who, although themselves acquainted with the different types of insanity in their fully developed forms, yet do not recognise the early symptoms, and they often suggest, under a misapprehension, that patients in the early stages of insanity should enter these so-called "homes," where they receive no benefit. I believe there are some consulting physicians who also recommend these homes for the early stages of insanity, which shows the urgent necessity there is for some intermediate place and for an immediate change in the law. The Lunacy Commissioners are compelled to see that the law is carried out in regard to the treatment of the insane, yet they are loth to take steps to prosecute those who may be acting in the supposed interests of their patients. The line between sanity and insanity is so fine and the neutral territory between the two is so indistinct and ill defined that cases of confirmed insanity remaining uncertified certainly do exist, and in greater numbers than is generally believed. We know that cases of scandal, of suicide, and of coroners' inquests do occur, and the wonder is they are not more numerous. If I may be permitted to say so, this is a compliment to the manner in which the high lunacy officials perform their difficult and delicate duty—viz., the safeguarding of the interests of the insane. Some of these cases are undoubtedly difficult to treat, and those presenting dangerous delusions, those with homicidal or suicidal tendencies, should receive asylum care from the start, but there should be a possibility of keeping others of them under care for a time, at any rate, until a correct diagnosis of the case has been made, and to avoid abuse the patients kept during this probationary period should be carefully inspected, and the "house" or "home" recognised or registered for official supervision either by the Lunacy Commissioners or by such an authority as the London County Council in London, who now propose to register places for massage, rest cures, and "lying in."

It is firmly believed that the feeling of not having to go into an asylum would diminish the unwillingness there is now on the part of mental cases to seek early relief. It is known that when early relief is sought the duration of the illness is also shortened.

Results of Early Treatment in England and Scotland.

Let us consider what has already been attempted in this direction. In 1908 an effort was made to establish mental wards in the Edinburgh Royal Infirmary for the reception and treatment of early mental cases, but financial difficulties compelled its set in authority over him. We hope that the Ilford district council will now realise that persistent efforts to dislodge a responsible official because his views of public duty conflict with theirs are not for the good of the community. We have dwelt upon the Ilford dispute at such length because it shows the need for taking out of the hands of local authorities the appointment and dismissal of medical officers of health.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on Jan. 8th, Sir RICKMAN J. GODLEE, the President, being in the chair.

Mr. Walter G. Spencer was introduced, made a declaration in the terms of the oath prescribed by the Charter of 1800, and was readmitted a member of the Court of Examiners.

The PRESIDENT stated that Sir Watson Cheyne, Bart., had consented to deliver the next Hunterian Oration, and accordingly he declared Sir Watson Cheyne Hunterian orator for 1915.

A letter was read from Mrs. Sydney Jones thanking the Council for their expression of sympathy on the occasion of the death of her husband.

A vote of thanks was given to Mrs. King, of Milton, Mass., U.S.A., for presenting a clock to the College in memory of her father, the late Dr. W. F. C. B. Fifield, M.R.C.S., of Boston.

Mr. Charters J. Symonds was appointed a representative of the College on the Council of Queen Victoria's Jubilee Institute for Nurses for three years.

A report from the Committee of Management was received and adopted. It was as follows:—

1. The Committee of Management have considered a recommendation of the examiners for the Diploma in the Diseases and Hygiene of the Tropics, that [illegible] two parts, and as the committee are of [illegible] adopt this proposal, they recommend [illegible] be substituted for Clauses I. to III. of the existing regulations, viz.:—

I. The examination will be held in the months of April and July.

II. The examination will consist of two parts.

Part I. will comprise—(*a*) written questions; (*b*) oral questions; and (*c*) practical laboratory work in the following subjects: [illegible] ogy, bacteriology, general parasitology, [illegible]

P[illegible] written questions; (*b*) oral questions; and (*c*) clinical and laboratory work in tropical diseases and hygiene. This will include helminthology, protozoology, zoology, and entomology in their relations to clinical medicine.

III. The fee for admission to Part I. is £5 5*s*., and the fee for admission to Part II. is £4 4*s*.

IV. Candidates may enter for Parts I. and II. separately, or together, but they will not be allowed to proceed to Part II. until they have passed Part I.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

BEGINNING with the current week the recently extended city of Exeter will be added to the list of towns for which statistics are published in the weekly return of the Registrar-General. In these 97 towns, each of which had a population exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 9199 births and 6703 deaths were registered during the week ended Saturday, Jan. 10th. The annual rate of mortality in these towns was equal to 19·3 per 1000, against rates steadily rising from 13·2 to 18·6 per 1000 in the five preceding weeks in the former 96 towns. This is the highest death-rate recorded for the aggregate of these towns since the sixth week of the year 1912. Among the several towns the annual death-rate last week ranged from 8·7 in Barrow-in-Furness, 8·8 in Hornsey, 10·3 in Ilford, 10·4 in Walthamstow, and 10·6 in Southend-on-Sea, to 28·1 in Great Yarmouth and in Norwich, 28·7 in Swansea, 30·8 in Stockton-on-Tees, 31·2 in Bath, and 32·1 in Wolverhampton.

The 6703 deaths from all causes were 328 in excess of the number in the previous week, and included 355 which were referred to the principal epidemic diseases, against 348 and 346 in the two preceding weeks. Of these 355 deaths, 89 resulted from infantile diarrhœal diseases, 66 from measles, 65 from diphtheria, 64 from whooping-cough, 43 from scarlet fever, and 28 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·0 per 1000, and coincided with that recorded in each of the three preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 96, 89, and 80 in the three preceding weeks, rose to 89 last week; of this number 23 were recorded in London, 6 in Birmingham, 6 in Manchester, 5 in Stoke-on-Trent, 5 in Liverpool, and 4 in Middlesbrough. The deaths referred to measles, which had been 62, 80, and 76 in the three preceding weeks, further declined to 66 last week, and included 8 in Burnley, 7 in London, 5 in Sheffield, 5 in Middlesbrough, and 4 each in Bradford, Barnsley, and South Shields. The fatal cases of diphtheria, which had been 69, 60, and 64 in the three preceding weeks, were 65 last week, of which 11 occurred in London, 8 in Birmingham, 5 in Sheffield, and 3 each in Portsmouth, Northampton, Liverpool, and Manchester. The deaths attributed to whooping-cough, which had been 56, 61, and 76 in the three preceding weeks, declined to 64 last week, and included 12 in London, 10 in Birmingham, 6 in West Ham, 4 in Liverpool, and 4 in Leeds. The deaths referred to scarlet fever, which had been 38, 38, and 34 in the three preceding weeks, rose to 43 last week; of this number 8 were registered in Salford, 6 in Sheffield, 4 in London, and 2 each in Ipswich, Birmingham, Manchester, Preston, and West Hartlepool. The fatal cases of enteric fever, which had declined from 26 to 16 in the four preceding weeks, rose to 28 last week, of which 5 occurred in London, 4 in Liverpool, 2 in Stockport, 2 in Sheffield, and 2 in Hull.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had fallen from 4143 to 3874 in the five preceding weeks, had further declined to 3757 on Saturday last; 416 new cases were admitted during the week, against 458, 326, and 425 in the three preceding weeks. These hospitals also contained on Saturday last 1081 cases of diphtheria, 219 of whooping-cough, 55 of measles, and 54 of enteric fever, but not one of small-pox. The 1779 deaths from all causes in London were 164 in excess of the number in the previous week, and were equal to an annual death-rate of 20·5 per 1000. The deaths referred to diseases of the respiratory system, which had been 307, 280, and 423 in the three preceding weeks, further rose to 511 last week, and were 211 in excess of the number recorded in the corresponding week of last year.

Of the 6703 deaths from all causes in the 97 towns, 223 were attributed to various forms of violence, and 560 were the subject of coroners' inquests. The causes of 52, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, and in 65 other smaller towns. Of the 52 uncertified causes of death, 12 were registered in Birmingham, 8 in Liverpool, 3 in Burnley, and 3 in South Shields.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,295,800 persons at the middle of this year, 1398 births and 889 deaths were registered during the week ended Saturday, Jan. 10th. The annual rate of mortality in these towns, which had increased from 15·6 to 20·3 per 1000 in the five preceding weeks, slightly declined to 20·2 per 1000 in the week under notice. During the 14 weeks included in the December quarter of last year the mean annual death-rate in these Scotch towns averaged 15·9, or 1·7 per 1000 above the corresponding rate recorded in the 96 large English towns. Among the several towns the death-rate last week ranged from 11·0 in Ayr, 13·8 in Perth and in Motherwell, and 14·4 in Leith, to 28·1 in Clydebank, 31·5 in Coatbridge, and 32·8 in Paisley.

The 889 deaths from all causes were 8 in excess of the number in the previous week, and included 79 which were referred to the principal epidemic di[illegible] 78 and 85 in the two preceding weeks. Of the[illegible] from measles, 14 from diphtheria, 12 [illegible] diseases, 9 from scarlet fever, 5 from whooping-cough, and [illegible] from enteric fever, but not one from small-pox. These 79 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·8, against 1·0 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 39, 37, and 50 in the three preceding weeks, declined to 36 last week, and included 15 in Glasgow, 6 in Paisley, 5 in Edinburgh, 3 in Greenock, 2 in Leith, and 2 in Kirkcaldy. The deaths referred to diphtheria, which had been 12, 10, and 12 in the three preceding weeks, rose to 14 last week, of which 6 occurred in Glasgow, 3 in Edinburgh, and 2 in Aberdeen. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 14, 9, and 11 in the three preceding weeks, were 12 last week, and included 3 in Aberdeen, 3 in Coatbridge, 2 in Glasgow, and 2 in Edinburgh. The deaths attributed to scarlet fever, which had declined from 12 to 7 in the four preceding weeks, rose to 9 last week, and comprised 4 in Edinburgh, 2 in Glasgow, 2 in Aberdeen, and 1 in Clydebank. The deaths referred to whooping-cough, which had been 3, 11, and 5 in the three preceding weeks, were again 5 last week; 2 deaths were registered in Edinburgh, 2 in Coatbridge, and 1 in Paisley. The 3 fatal cases of enteric, [illegible] erwell [illegible] n the [illegible] stem, [illegible] veeks, [illegible] were attributed to various forms of violence, against 31 and 30 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 640 births and 588 deaths were registered during the week ended Saturday, Jan. 10th. The annual rate of mortality in these towns, which had been 18 9, 15 9, and 25 7 per 1000 in the three preceding weeks, declined to 25·4 per 1000 in the week under notice. During the 14 weeks included in the December quarter of last year the mean annual death-rate in these Irish towns averaged 17·8 per 1000; in the 96 large English towns the corresponding rate did not exceed 14 2, while in the 16 Scotch towns it was equal to 15 9 per 1000. The annual death-rate last week was equal to 26 3 in Dublin (against 20 5 in London and 18 4 in Glasgow), 26 5 in Belfast, 29 2 in Cork, 14 0 in Londonderry, 16 2 in Limerick, and 30 4 in Waterford, while in the 21 smaller towns the mean death-rate was 23 6 per 1000.

The 588 deaths from all causes were 5 fewer than the number in the previous week, and included 44 which were referred to the principal epidemic diseases, against 31 and 32 in the two preceding weeks. Of these 44 deaths, 13 resulted from scarlet fever, 8 from measles, 7 from infantile diarrhœal diseases, 6 from diphtheria, 5 from whooping cough, and 5 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1 9 per 1000; in the 97 large English towns the [illegible] weeks, rose to 13 last week, and comprised 12 in Belfast and 1 in Clonmel. The deaths referred to measles, which had steadily risen from 1 to 7 in the five preceding weeks, were 8 last week, of [illegible] ıtal cases of diarrhœa a [illegible] 2 years), which had bee [illegible] ıg weeks, were 7 last we [illegible] lin, 2 in Belfast, and 2 ı [illegible] to diphtheria, which [illegible] preceding weeks, were 6 last week, and comprised 4 in Belfast and 2 in Dublin. The 5 deaths referred to enteric fever, of which 3 [illegible] e weekly [illegible] the fatal [illegible] 7 in the three preceding weeks, further declined to 5 last week, 3 of which occurred in Belfast. In addition to the above, 2 deaths from typhus were registered in Belfast.

The deaths referred to diseases of the respiratory system, which had been 80, 89, and 162 in the three preceding weeks, declined to 154 in the week under notice Of the 588 deaths from all causes, 169, or 29 per cent, occurred in public institutions, and 15 resulted from various forms of violence. The causes of 26, or 4 4 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0 8 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Connell has taken up duty at Liverpool, on transfer from Shrewsbury. Captain A. S. Arthur has been transferred from Wrexham to the

Military Hospital at Newport. The following Captains have joined the Royal Army Medical College at Grosvenor-road, S.W., for the courses of instruction for promotion to the rank of Major: J. W. L. Scott (from Netley), W. C. Smales (Portsmouth), A. H. Bond (Limerick), and A. C. Vidal (Aldershot). Captain M. B. H. Ritchie has arrived home, tour expired, for duty from India. Captain C. P. O'Brien-Butler has been appointed to the Irish Command for duty. Captain L. V. Thurston has been transferred from the Cambridge Hospital at Aldershot to the Military Hospital at Bordon. Captain M. J. Cromie has taken up duty at the Military Hospital, Maidstone, on transfer from Chatham. Captain G. P. A. Bracken has arrived home for duty from Malapurram Cantonment. Captain W. H. O'Riordan has been appointed to Dehra Dun for a course of Instruction in Radiography, on transfer from the Military Hospital at Murree Cantonment. Captain H. Gall has joined at Sialkot. Captain C. R. Millar, on arrival in the Irish Command on Jan. 23rd, will be appointed to the Cork District for duty. Captain J. W. Houston has been transferred from the Military Hospital at Cherat Cantonment to Peshawar. Captain A. M. Bennett has arrived home, tour expired, for duty from India. Captain C. Ryles has been appointed to the Alderney District for duty. Captain A. L. Foster has been placed under orders for transfer from the Second (Rawal Pindi) Division of the Northern Army in India to the Military Hospital at Aden, vice Captain W. F. Loughnan, tour expired. Captain G. B. Edwards has been transferred from Leicester to the Military Hospital at Shorncliffe. Captain E. C. Phelan has taken up duty at the Military Hospital, Barrackpore, on transfer from Dinapore Cantonment. Captain J. E. H. Gatt, attached to the Station Hospital at Allhabad Cantonment, has been directed to proceed to Benares Cantonment to take charge of the Military Hospital, vice Captain A. Irvine-Fortescue, proceeding to Japan to study the Japanese language. Captain F. W. M. Cunningham has been transferred from the Military Hospital at Kalabagh to Sialkot. Captain M. Keane has taken up duty at Reading. Captain T. W. Browne has arrived home for duty, tour expired, from India. Captain L. Murphy has been transferred from the Military Hospital at Bangalore Cantonment to Malapurram, Madras Presidency. Captain G. G. Collett has taken up duty at Karachi Cantonment on transfer from the Military Hospital at Quetta.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotion by brevet: Major Thomas Arthur Granger to be Brevet Lieutenant-Colonel (dated Jan. 1st, 1914).

Colonel J. Crimmin, V.C., C.B., C.I.E., has been transferred from duty under the Home Department of the Government of India, and appointed Assistant Director of Medical Services to the Derajat and Bannu Brigades, vice Colonel J. Grayfoot, transferred.

Lieutenant-Colonel H. W. Pilgrim has been granted general leave of absence home from India to May 10th next. Lieutenant-Colonel R. C. MacWatt has been appointed Agency Surgeon to the Eastern Rajputana States. Lieutenant-Colonel F. O'Kinealy has been appointed Surgeon Superintendent of the Presidency General Hospital at Calcutta.

Major P. F. Chapman, civil surgeon at Nagpur, has been appointed Superintendent of the Lunatic Asylum at Nagpur. Major J. H. Hugo, D.S.O., has been appointed Agency Surgeon at Baghelkhund by the Foreign Department of the Government of India. Major H. de V. Condon, on return from leave of absence, has been appointed Civil Surgeon at Hazara. Major H. Kirkpatrick has taken up duty in Madras. The services of Major R. B. B. Foster have been placed permanently at the disposal of the Government of Madras. Major J. Husband has been appointed to hold civil medical charge of the Wano Agency. Major R. P. Wilson has been appointed to officiate as Superintendent of the Campbell Medical School and Hospital at Sealdah during the absence on leave of Major J. W. F. Rait. Major F. D. S. Fayrer has been granted combined leave of absence home from India for 15 months.

Captain F. H. Salisbury, officiating superintendent of the Central Prison at Dacca, has been granted combined leave of absence home from India for six months. Captain F. P. Connor, on return from leave of absence, has been appointed to officiate as Civil Surgeon and Sanitary Officer at Saran. Captain A. N. Thomas has been granted leave of absence home from India for eight months on medical certificate. Captain M. S. Irani has been appointed to officiate as Civil Surgeon at Sukkur. The services of Captain O. A. R. Berkeley-Hill have been placed temporarily at the disposal of the Government of Madras. Captain H. W. Pierpoint has been appointed medical officer to the Turco-Persian Frontier Commission. Captain J. Anderson has been appointed to hold civil medical charge at Meranshah. Captain R. E. Wright has joined the Bacteriological Department. Captain A. S. Leslie has been appointed to officiate as Assistant Superintendent at the Government Maternity Hospital, Madras. Captain H. Crossle has been granted combined leave of absence home from India for five months. The services of Captain E. C. Hodson have been placed temporarily at the disposal of H.E. the Governor of Madras Presidency. Captain F. R. Coppinger has taken over medical charge of the Civil Prison at Aden. Captain F. C. Fraser has been appointed to officiate as Superintendent of the Central Prison at Vellore. Captain H. S. Hutchinson has been appointed to officiate as Professor of Physiology, Histology, and Hygiene at the Grant Medical College, Bombay, during the absence on leave of Major L. T. R. Hutchinson.

TERRITORIAL FORCE.

Royal Army Medical Corps.

For Attachment to Units other than Medical Units.—John Saffley to be Lieutenant (dated Jan. 7th, 1914).

THE TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon the undermentioned officers of the Territorial Force:—

Royal Army Medical Corps.

Lieutenant-Colonel Sydney Arthur Monckton Copeman, F.R.S., Sanitary Officer of the 1st London Territorial Division.

2nd East Anglian Field Ambulance, Royal Army Medical Corps: Lieutenant-Colonel John Herbert Stacy.

1st South Midland Field Ambulance, Royal Army Medical Corps: Transport Officer and Honorary Major George H. Dawes. Major John Henry Harris attached to the 4th Wessex Brigade, Royal Field Artillery. Major Francis James Warwick, attached to the 8th (Cyclist) Battalion, the Essex Regiment. Major Henry Dutch, attached to the 4th (City of London) Battalion, The London Regiment (Royal Fusiliers).

DEATHS IN THE SERVICES.

Major Ernest Chester Anderson, D.S.O., late R.A.M.C., at Totland Bay, in his fifty-second year. He entered the army in 1892 and served in the South African war. He was present at the relief of Kimberley [illegible] Orange Free State, includin [illegible] (mentioned in dispatches, [illegible] Queen's medal with four [illegible] two clasps). He reached the rank of major in 1904 and retired in 1912.

WEST AFRICAN MEDICAL STAFF.

The [illegible] African Medical Staff will dine togeth [illegible] n. 21st, at 7.45 P.M., in the Walnu [illegible] London, under the chairmanship of the president, Mr. J. P. Fagan.

ROYAL WATERLOO HOSPITAL ARMY COT.

Prince Alexander of Teck is making an appeal for funds for the endowment of a cot in the Royal Waterloo Hospital for the sick child of any discharged soldier living in London.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The January issue of this journal, the first number of the twenty-second volume, contains, among other articles, two communications of interest with regard to milk problems. The first, an Investigation into the Keeping Properties of Condensed Milks at the Temperature of Tropical Climates, by Lieutenant-Colonel W. W. O. Beveridge, D.S.O., concludes with the expression of opinion that the change in colour of certain kinds of condensed milks in tropical climates is presumably due to brown colour being developed by sugars which reduce in solution at a certain temperature. It is recommended that only those brands of unsweetened milks which have been proved to. be sterile should be selected for use in tropical climates. The second article is a preliminary note on the Presence of Agglutinins for the Micrococcus Melitensis in the Milk and Blood Serum of Cows in London, by Major J. C. Kennedy. The author prefixes a note of warning to his article explaining that he does not wish to appear as an alarmist, nor as being understood to say that, because in high dilutions the milk and the blood serum of certain cows in London dairies agglutinate the micrococcus melitensis, the cows are therefore capable of transmitting undulant fever. In Pulmonary Tuberculosis in the Royal Navy, with Special Reference to its Detection and Prevention, Surgeon Campbell Ross, R.N., while admitting that pulmonary tuberculosis is still a very common disease in the Royal Navy, states that all indications go to prove that it is on the decrease, and he looks forward with confidence to a time in the future when pulmonary tuberculosis will be one of the incidental diseases in the British Navy. In "Man and Nature" Colonel R. H. Firth gives us another of his delightful musings of a philosophical nature. In the present instance his reflections deal with the emotions produced by contemplating nature in "her grandest, most awe-inspiring, and even mystical aspects."

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 139.)

XXXIV.—BRISTOL: THE REFEREE AND REVISED DRUG BILLS.

BRISTOL is one of the towns where there was considerable opposition against the Act and where some advantage was secured as a result. The members of the profession began to hold meetings on the question of insurance two years before the Act was adopted. Then the Bristol delegates at the Birmingham meeting of the British Medical Association complained that the war chest was not full, but sought legal opinion to ascertain whether the Association had the legal right to organise what was practically a strike fund. Though the legal opinion obtained proclaimed that the money was safe, a medical federation was started so as to have a fund more safely secured, and this organisation obtained recognition from the Board of Trade as a limited company, with an existence quite independent from the Association. This was considered safer than registering as a trade union. The scepticism of the Bristol practitioners did not please the British Medical Association. The latter, deeming that their money scheme was good enough for everybody, decided against immediate coöperation with the Bristol Federation. The Bristol practitioners felt they had an opportunity of going forward and of obtaining considerable sums of money, yet if they collected subscriptions at the same time as the Association, and for the same strike fund purposes, they would damage both funds. The Bristol Federation, to its regret, reluctantly had to acknowledge it was bound to support the general effort. For the sake of unity and discipline its members abandoned their enterprise and their good opportunity of creating a safe and strong local fund. The Federation rules were that every member rendered himself responsible for a minimum subscription of £2 and a guarantee of £5—this, at least, was the figure mentioned to me. In any case, none of the money was called up, and those who had given promises were asked to transfer their subscription to the British Medical Association. In doing this it is claimed that the Bristol practitioners gave more in proportion than the practitioners of any other town in England.

In November, 1912, when the agitation against the Act was at its height, there were in the Bristol Division of the British Medical Association 421 practitioners, and of these 276 subscribed. Though in November of that year they only actually paid in £293 19*s.* they guaranteed £4488 5*s.* The votes given were as emphatic as the money subscribed, *both proving how strong was the feeling against* the Act. At the meeting held on Dec. 20th, 1912, only 3 out of 417 votes recorded were in favour of accepting panel service. These three voters were, however, perfectly loyal to the majority, maintaining discipline while expressing their individual opinion. Bristol claims that it brought forward a greater number of medical men against the panel and subscribed a larger sum for the strike fund than any town in England, yet when on Christmas Eve a small group of practitioners announced that they felt obliged to go on the panel, all the others, doubting the adequacy of the available "strike funds," found themselves compelled to follow suit. This was not formally decided upon, however, until certain special privileges had been obtained for the Bristol Panel Service. With all this it sufficed for one single practitioner to declare on Christmas Eve that he must go on the panel, and thereupon the entire resistance collapsed. Another practitioner announced he would in that event be obliged to follow suit, and so would all the rest.

Satisfactory Constitution of Medical Committees.

In the face of this defection, and seeing that they could not hold out, the Bristol practitioners nevertheless managed to obtain special terms. Among the various concessions made by the English Commissioners as a condition for the formation of a panel at Bristol was the appointment of a referee, or medical adviser, as he is here called. Also it was agreed that all matters concerning medical men should be submitted to a medical subcommittee, consisting of five representatives of the Local Medical Committee and five representatives of the Insurance Committee, with a town councillor as chairman. The referee has an annual income, and the great point is that his nomination does not depend on the Insurance Committee, for he is chosen by the Medical Committee. On this committee the non-panel practitioners are well represented.

At first there was a great bitterness of feeling between the practitioners on the panel and those who held aloof, but when it was found that the former made room on the Medical Committee for the latter peace was re-established. To-day, even on the special Panel Committee to be formed in accordance with the amendments to the Act, six non-panel practitioners are to be appointed. This is a clear proof of the friendly feelings that to-day prevail on both sides. Not many in Bristol among the extreme opponents of the Act would now like to see it abolished. Certainly there remains room for improvement. It is thought, for instance, that the Insurance Committee is not sufficiently influenced by the Medical Committee. As a local practitioner exclaimed in my presence: "The doctors sell their labour, but have hardly any voice in the bargain."

Bristol is divided into seven groups or districts, which originated with the British Medical Association and were adopted by the provisional Medical Committee that emanated therefrom. Ultimately the Insurance Commissioners endorsed this method of election. The rule, roughly speaking, is that there should be one elected out of every ten medical men practising in the town. There are 34 members on the Local Medical Committee. The Panel Medical Committee is to be elected by groups according to the strength of the panel men belonging to these groups, and this will be a much larger committee i[illegible]ers represented. *As* [illegible]mittee, it has had a ha[illegible] problems and a great quantity of trifling routine work.

The First Referee.

It is in the appointment of a referee, however, that Bristol stands prominent. The initiative taken here has since been followed at Oxford and Plymouth, but to Bristol belongs the credit of having set the example. Nor was it an easy matter. Thus each Friendly Society wanted to have a referee of its own, presumably to quarrel one with the other. Then a pertinent question was asked as to who should pay the referee. The admitted that the general statement of the case was correct, though the numbers were not authenticated. It appears that the education committee some time ago asked the council to authorise the expenditure of £500 to establish an open-air school and that the council did not approve the proposal. The matter will be brought up again.

Some Statistics regarding School Children.

Some interesting statistics have been published regarding the school children of Manchester. An examination of 500 boys and 500 girls of 13 years of age shows that the average height of the boys in poor-class schools was 52 inches, in medium schools 54, and in good schools nearly 57. In poor schools the average weight was 70 lb., in medium schools 73¾ lb., and in good schools nearly 82 lb. The figures for girls were: height, 54, 54, and 57 inches respectively, and their weights were 75 lb., 77 lb., and 83 lb.

Jan. 12th.

SCOTLAND.

Scottish Poor-law Medical Officers' Association.

THE report of the committee of this association for the year 1913 has just been issued from the headquarters at Glasgow. The work of the year is briefly summarised under the headings Vacant Appointments, Appeals to the Association, Pulmonary Tuberculosis Regulations, the Insurance Act, &c. The death of the treasurer, Dr. Matthew Martin, is recorded with regret. The annual meeting will be held to-day (Friday, Jan. 16th) at the St. Enoch Hotel, Glasgow, at 4.30 P.M. An effort is being made to enlarge the membership of the association, and members of the Poor-law medical service in Scotland are asked to communicate with the secretary, Mr. W. L. Muir, 1, Seton-terrace, Glasgow East.

A Scottish Hospital Exhibit.

At the International Kinematograph Exhibition and Conference to be held in Glasgow from Feb. 17th to 26th next there is to be an exhibition of models, plans, photographs, furniture, surgical equipment, and other things connected with hospital work. The main object of this exhibit is to bring together a collection of articles illustrating new features in construction, equipment, or working.

Granite Trade and Phthisis.

Attention has again been directed in Aberdeen to the prevalence of consumption among workers in the granite yards. A prominent member of the Aberdeen granite trade says difficulty is experienced in getting the men to wear respirators, even although they admit their usefulness. Even the lighter and more comfortable and modern respirators are thrown aside at the first opportunity. The real remedy lies in preventing the dust from getting into the atmosphere, and large roomy, airy sheds would do much towards fighting the prevalence of the disease. The new sheds, though more comfortable in winter, are not so free from dust as the old-fashioned variety, but the medical officer of health thinks they are really better than the old ones, because of the men's immunity from chills and draughts. There is no doubt that masters would coöperate with the men, and would welcome any scheme by which the men's health would be improved. In the opinion of one of the workers, who takes a keen interest in the matter, what the men really want is the interference of a Government Department to make regulations with regard to the dust problem. The men will not wear the big "air veil" because of its size and clumsiness. The respirators they might wear if they were not clumsy, and the piece of cotton-wool over the nostrils and mouth idea commended itself as effective and simple. The true remedy in his opinion, however, lay in prevention of dust getting into the atmosphere.

Medical Service in the Highlands.

At a meeting representative of the various public bodies in Orkney held on Jan. 9th, to consider the replies to the schedule issued by the Highlands and Islands Medical Service Board, it was unanimously agreed to ask for a grant to modernise and extend the General Hospital at Kirkwall, and it was also agreed by a majority to ask for grants for a hospital at Stromness and at North Ronaldshay. It was agreed to start a nursing service in those districts where there was no resident medical practitioner. It was also agreed by a large majority that a special board should be created to administer the medical fund locally, this board to consist of a committee of seven members of the county council, who would consult members from parish councils, medical associations, the Insurance Committee, and town councils. The whole scheme was remitted to the count councillors on the committee for final adjustment when an estimate of the total cost will be forth coming. On Jan. 9th at Inverness a conferenc was held of the various bodies in the county Inverness specially interested in the question medical service. Over 100 representative delegat from the mainland and islands were present. Th needs of the districts were fully discussed, an the opinion of the majority was that provisio should be made for a number of medical men sufficient for the various districts of the count with adequate accommodation and means o travelling to the various parts of their districts provision for consultation between medical men in serious cases and for specialised service; and provision for hospitals and nursing services at suitable centres, for means of communication between medical men and hospitals in scattered districts, and for conveyance to hospital. A protest was entered against remitting to the districts to deal with the question, as against a central committee, but the majority seemed in favour of dealing with the medical board as districts.

Jan. 13th.

IRELAND.

The National Insurance Act.

EACH doctor on the panel in Ireland has received a letter from the National Health Insurance Commission (Ireland), dated Jan. 6th of this year, pointing out, in reference to the term of agreement for certification which expired on Jan. 14th, that the Commission, in view of the negotiations at present in process, propose to continue the existing panel arrangements up to the end of the financial year—March 31st, 1914—on the terms and conditions mentioned in the previous agreement, and the Commission would be glad to learn if the panel doctors are willing to continue to serve for this further period. Further, it is announced that steps are being taken to have payment made to the several panel doctors for the services already rendered by them.

Association of Tuberculosis Officers.

A meeting of Irish tuberculosis officers was held recently in Dublin for the purpose of forming an association. It was unanimously decided to form such an association, its object being to examine the various problems arising in connexion with tuberculosis, and to protect the interests of the members. Mr. A. Lanigan O'Keeffe, of co. Tyrone, was elected chairman, and Mr. P. J. Burke, of co. Sligo, and Mr. M. Quinlan, of co. Kerry, joint honorary secretaries.

Military Distinction for an Irish Practitioner.

Mr. Charles Ronayne, of Youghal, co. Cork, served in the French lines as surgeon to an ambulance during the Franco-Prussian war, and the French Minister for War recently intimated to him that he intended conferring on him a medal in appreciation of his services. The medal was handed to the British Ambassador at Paris with a request that he would have it forwarded to Mr. Ronayne. Accordingly in due course the medal was presented to him by the French Consul at Dublin. Mr. Ronayne put himself in communication with the Secretary of State for Foreign Affairs, who, in reply, informed him that the King had been graciously pleased to allow him to wear the medal.

The Late Dr. C. J. Clibborn.

The death occurred suddenly on Jan. 4th of Dr. Cuthbert J. Clibborn, formerly a medical inspector of the Local Government Board of Ireland. He was 68 years of age. Born of an old Quaker family of the co. Westmeath, he was educated at Trinity College, Dublin, where he graduated M.B. in 1869. He subsequently practised in co. Wicklow. On his appointment as an inspector of the Local Government Board he was stationed in Belfast, and had charge for some time of the whole province of Ulster. At a later date it was found necessary to make the areas of inspection smaller. He retired from office three years ago. Dr. Clibborn was much respected as an official both by the members of his own profession and by the general public.

The Late Dr. J. C. Ferguson.

It is with sincere regret I announce the sudden death on Jan. 6th of a well-known and highly respected Belfast dispensary doctor, Dr. James C. Ferguson, at the comparatively early age of 58 years. His most intimate friends and relatives had not the slightest suspicion that he was in any way the subject of organic heart disease. Dr. Ferguson was born at Doagh, o. Antrim, where his father was a much espected surgeon. Having decided to follow in his father's footsteps, Dr. Ferguson studied at Queen's College, Belfast, where he had a most xcellent record, and in 1884 he graduated M.D. and M.Ch. of the late Royal University of Ireland, while n the next year he obtained the M.A.O. degree. The ollowing year he was appointed resident medical officer in the Belfast union infirmary, and in July, 888, he was selected as dispensary medical officer of Dock ward, while a few years ago he was transerred to the Ormeau ward district, of which he was dispensary medical doctor, and registrar of births, deaths, and marriages of No. 6 district. He was also physician to the Ulster Hospital for Women and Children. He was a great favourite with all in the Poor-law service. At a meeting of the Belfast local medical committee a special vote of condolence with Mrs. Ferguson was passed, on the motion of the chairman (Sir John Byers), seconded by Sir Alexander Dempsey.

Jan. 13th.

PARIS.

Insanity Statistics in Paris.

Dr. Auguste Marie, medical director of the Insane Asylum of Villejuif, has published some interesting statistics of insanity in Paris with special reference to occupation. The classification made by Parchappe some 50 years ago has long held sway. According to it the liberal professions always furnished the greatest number of insane; then in decreasing order came soldiers, sailors, domestic workers, people of private income, landowners, industrial workers, agriculturists, merchants, and tradespeople. Social evolution, by modifying the conditions of various occupations, has brought about important changes in this order, which, however, are not always the same in all countries. Among professional men the intoxications play a daily increasing rôle, while general paralysis consequent on syphilis claims more and more numerous victims among the middle classes and the rich, whatever their occupation. Dr. Marie's statistics deal with the cases of mental alienation observed recently in the population of Paris, and confirm this evolution; and the interesting point is the recorded percentage borne in each occupation in comparison with that of the total population. In stone-working trades, which furnish a considerable and altogether unexpected percentage, 492 insane are found out of 24,012 workers, or 2·04 per cent. In occupations dealing with the animal kingdom (drivers and stock-raisers) are found 671 insane out of 57,891, or 1·17 per cent. In chemical industries, or from lead intoxication, 649 cases of insanity in 63,220 persons, or 1·02 per cent. Among *commis-voyageurs* there are 1072 insane out of 37,398 persons who make their living thereby, or 2·85 per cent. The liberal professions and sedentary commercial occupations, which formerly headed the list, now give only 1·02 per cent. The occupations least affected by insanity are industries connected with the timber trade, with transport, and with alimentation, whose percentages vary from 0·48 to 0·85. On the whole, the class of workers is much more affected with dementia than used to be supposed before statistics were collected on this principle. Dr. Marie, it is true, includes in insanity very diverse mental ailments which were not formerly comprised therein when only dementia pure and simple was recorded; for instance, he includes in his statistics mental debility, mania, melancholia, enfeeblement of intellect, alcoholic insanity, and parasyphilis. The rôle played by alcoholism in the genesis of dementia in France is considerable, and is continually increasing in all the asylums in the country. Dr. Marie records a very curious new observation, viz., the increase of cases of madness in the various industrial occupations, due to the excitement of social conflicts and the Syndicalist struggle. The degenerates, who are to be found in all classes of society, accentuate the tendency to violence. Some of this class were found among the Post-office employees at the time of the strike of 1908–09. These were really feeble-minded persons, victims of moral shock due to the perturbations and diverse mental preoccupations occasioned by the strike. Dr. Marie thinks that these troubles may convert such subjects into leaders or inspirers of violence, such as is general enough in strikes, especially when accompanied by alcoholic excitement. He does not assert that all the leaders are of this class, though a certain number of them are.

already high digitalis has no power to raise it any higher.

For some years I have used digitalis in high-pressure cases—pressures varying from 200 mm. to 280 mm. Hg—and in no case have I had any untoward result. By that I mean to say that I have never seen the pressure rise under the digitalis treatment, nor have I seen a single case of cerebral, retinal, or other hæmorrhage during the treatment. I may, of course, have been fortunate in my selection of cases, but I find that what I have stated has been experienced by others as well as by myself.

Practically in every case there has been vast improvement—for a time at any rate. Naturally enough, the time comes when the heart refuses to react to digitalis at all. The doses used were not the minute and generally useless ones so often employed—namely, 3-5 minims of digitalis tincture three times daily (larger doses being so generally supposed to raise still farther an already high pressure) but doses of 15 minims of the tincture every four or six hours until the desired effect is produced. I have found that the better the result from the use of digitalis the healthier the cardiac musculature. Conversely, that the poorer the result from the use of the drug the more fibrotic the state of the cardiac structures.

As the subject is not a brief one, probably an example of a patient seen lately may convey more clearly my contention. On Boxing Day last I was asked to see Mrs. ——, aged 62, who was said to be in distress through her breathing. I found the patient in a state of orthopnœa. The slightest movement in bed increased the severe dyspnœa, showing that the "rest power" (MacKenzie) of the heart was exhausted. The forehead and face were deeply congested, the lips and ears cyanosed. The pulse was 110 and regular, save for a very occasional premature contraction, although premature contractions ought really to have disappeared with the increased pulse-rate. This occurrence is, I think, rare. The apex beat was 3½ inches outside the nipple line, and there was a clear systolic bruit in the mitral area, probably due to dilatation. There was also a systolic aortic bruit and a ringing aortic second sound. The patient complained of a feeling of constriction round the chest. The reading on the sphygmomanometer was 280 mm. Hg (the instrument was standardised and the reading was taken several times at short intervals). The vessels were moderately sclerosed.

This was a case where several things were obvious: (1) the state of the patient demanded immediate relief; (2) the risk of the advent of cerebral hæmorrhage was evident; (3) to have raised the pressure still farther (had such been possible) would have been still farther to court disaster; (4) the reduction of the pressure was imperative as it was above what the patient normally required, and the extra strain was crippling the left ventricle, apart from the other risks run. If, then, "it is the tension that determines the use of digitalis," and "if the tension be raised it (digitalis) will do harm"; if we are to accept these statements, this obviously was a case where digitalis ought certainly to have been withheld. The patient was ordered 15 minims of Parke, Davis, and Co.'s standardised tincture every six hours, along with sharp magnesium sulphate purges, a very limited milk diet, hot mustard foot baths, and a mixture containing spt. etheris, spt. ether. nitros., spt. chloroform., and spt. ammon. aromat., to relieve the breathing temporarily. In 24 hours the pulse was 94; the blood pressure had fallen to 220 mm. Hg, and the greater part of the dyspnœa had vanished. After 48 hours the digitalis was reduced to 10 minims every six hours until the pulse had dropped to 84, and then to 7½ and 5 minim doses until the rate was 76 and 74. On Jan. 6th the pressure was 200 mm. Hg (probably the normal—or necessary—for the patient), and all symptoms had disappeared; the breathing was easy and tranquil; the patient could move with ease; the malar turgescence had disappeared, and the pulmonary œdema was no longer present. This is only one case out of many where I have found exactly the same sequence of events; but it is typical of the group.

I must apologise for this long transgression on your space; but as these cases are numerous and their treatment important, and as general practitioners have to deal with many of them, the subject appears to me to be one of no little importance Not so long ago it was freely taught that t administer morphia in disease of the kidneys wa a dangerous, not to say fatal, proceeding, wherea morphia—and morphia alone—will frequently terminate the dangerous convulsions of uræmia It seems to me that the fear of giving digitalis in high-pressure cases is on a par with the now known to be erroneous teaching regarding morphi and renal disease. Strophanthus in my hands ha been a failure.

In a paper I read before the members of th Hunterian Society last year on this subject ther was no exception taken to these statements in th subsequent discussion—probably an indication tha the value of digitalis in this type of case is becoming more widely appreciated.

I am, Sir, yours faithfully,
A. GRAHAM-STEWART.

Cliftonville, Margate, Jan. 12th, 1914.

THE STERILISATION OF MILK AND ALLIED QUESTIONS.

To the Editor of THE LANCET.

SIR,—All who have had long and extensive clinical experience in the feeding and rearing of babes must agree with the frank and scientific leading article in THE LANCET (Jan. 10th, p. 118). Dr. J. E. Lane-Claypon's pamphlet mentioned: "They showed in the case of man and the lower animals alike that for the young of a given species there is an undoubted superiority—probably attributed to protein constituents—in milk derived from animals of that species over milk obtained from other species, whether sterilised or not."

In my work on "Feeding and Rearing of Children" (first edition, 1894) I write (Nature's Food, p. 26): "I think myself that among all animals who rear their young by the aid of milk there is a certain protein in the composition of such milk which is especially suitable for the requirements of the young of its species, and if recourse is had to the milk of one animal in order to feed the offspring of another there will be some deficiency in the growth and proper nourishment which soon becomes apparent, unless we can supply by artificial means the ingredient that is missing or deficient."

I may add that at that distant period I searched for any written opinion on the subject, but was unable to discover any.—I am, Sir, yours faithfully,

THOMAS DUTTON.
New Cavendish street, W., Jan. 10th, 1914.

To the Editor of THE LANCET.

SIR,—The evidence of the appalling effects of cooked milk upon the infant and child is so overwhelming to those who are in a position to appreciate the facts that it is terrible to think of the masses of children condemned to suffer such a diet. Owing to "the concurrent use of lemon or orange juice" to which you refer, the infant manages to survive *only that he may be further* plied with a profoundly unwholesome food. Every day I see children as ill as they can well be, with all sorts of mysterious diseases that have baffled their doctors—doctors who are good men at their work but who have not yet managed to grasp the fact that the elemental requirement of the offspring of all mammals is raw milk. It is too great a thing to attempt to cite the evidence in a letter, but I may cite certain documents. 1. Acute Intestinal Toxæmia in Infants, London, 1911. 2. The chapter on "The Bacteriology of Milk" in "The Nutrition of the Infant," London, 1913. 3. The Bacteriology of Alimentary Toxæmia in the Infant and Child.[1]

I may further cite the paper read by me before the New York Academy of Medicine on Nov. 13th, 1913, which is to be published on Feb. 1st, I am informed, in the *American Journal of Diseases of Children*, the title being "The Bacteriological Diagnosis and Treatment of Alimentary Disease in the Infant and Child." In these writings I describe diseased conditions which are of extremely frequent occurrence, and which cannot occur *in a child fed* on raw milk.

To prevent tuberculosis! Where is the surgeon who will advise a man to have his legs amputated in order that he may escape the danger of slipping upon orange peel? There is a violent contrast between the actual investigations of the Royal Commission on Tuberculosis and the Final Report. The investigations are overwhelmingly in favour of Koch's contentions. For the details I must refer those interested to my article in *Science Progress*, April, 1912, "Fallacies in the Report of the Royal Commission on Tuberculosis." "Fallacies" is a sufficiently mild word in the circumstances, for the Commissioners took the words of their scientific investigator, "bovine tubercle bacilli of human origin,"[2] and changed them into "bacilli of bovine source."[3]

I take this opportunity to express my high appreciation of the valuable contribution to the progress of scientific medicine which Mr. Robert Mond has made in his recent communication to the *Times*. May I be allowed to add a quotation from Robert Koch's address (1901)? "It is well known that the milk and butter consumed *in great cities* very often contain large quantities of the bacilli of bovine tuberculosis in a living condition, as the numerous infection experiments with such dairy products on animals have proved. Most of the inhabitants of such cities daily consume such living and perfectly virulent bacilli of bovine tuberculosis and unintentionally carry out the experiment which we are not at liberty to make. If the bacilli of bovine tuberculosis were able to infect human beings many cases of tuberculosis caused by the consumption of alimenta containing tubercle bacilli could not but occur among the inhabitants of great cities, especially children. And most medical men believe that this is actually the case.

In reality, however, it is not so. That a case of tuberculosis has been caused by alimenta can be assumed with certainty only when the intestine suffers first—that is, when a so-called primary tuberculosis of the intestines is found. But such cases are extremely rare. Among many cases of tuberculosis examined after death I myself remember having seen primary tuberculosis of the intestine only twice. Among the great post-mortem material of the Charité Hospital in Berlin ten cases of primary tuberculosis of the intestine occurred in five years. Among 933 cases of tuberculosis in children at the Emperor and Empress Frederick's Hospital for Children Baginsky never found tuberculosis of the intestine without simultaneous disease of the lungs and the bronchial glands. Among 3104 necropsies of tuberculous children Biedert observed only 16 cases of primary tuberculosis of the intestine. I could cite from the literature of the subject many more statistics of the same kind, all indubitably showing that primary tuberculosis of the intestine, especially among children, is a comparatively rare disease, and of these few cases that have been enumerated it is by no means certain that they were due to infection by bovine tuberculosis."

I am, Sir, yours faithfully,
RALPH VINCENT,
Senior Physician and Director of the Research Laboratory, the Infants' Hospital, London.
Harley-street, W., Jan. 10th, 1914.

TREATMENT OF GASTRIC AND DUODENAL PERFORATION.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Jan. 10th there appeared a paper by Mr. Edred M. Corner on this subject, in which the writer recommended a form of operation which, to my mind, is only justified on the rarest occasions.

Whilst in the title of the paper both gastric and duodenal perforations were included, in the text no direct reference was made to the latter type of case. Any form of operation which involves the establishment or even the risk of a duodenal fistula is essentially a bad operation, for there is no more rapid form of what may be called physiological death than that resulting from duodenal fistula.

It is reckoned that not less than five or six pints of fluid secretions are poured into the duodenum and reabsorbed lower down in the intestine in the 24 hours, and the rapid emaciation which follows the loss of even part of this secretion is very striking. In the Edinburgh statistics on 200 cases of perforated duodenal ulcer[1] there were three cases in which the perforation was not closed at the operation, but merely drained to the exterior. "All three cases died within a few days with rapid emaciation and asthenia, illustrating how imperative it is that the perforation be closed in one way or another at the operation." Whilst this danger does not exist in the case of gastric fistulæ, there are as rapid, and certainly cleaner, ways of dealing with the perforation than by tamponade.

In cases where the gastric wall around the perforation is so indurated and œdematous that invagination is impossible, the opening may be closed by a plug of omentum, as first recommended by Bennett.[2] In the rare cases of perforated duodenal ulcer in which invagination is impossible the same method may be employed or the gall-bladder may be stitched over the perforation. If the patient be submitted to operation within a few hours of the perforation all elaborate methods for draining the abdomen with gauze packs, &c., are unnecessary and may be harmful.

---

[1] Proceedings of the Royal Society of Medicine, May, 1913.
[2] Final Report, Part 2, Appendix, Vol. I, p. 532.
[3] Second Interim Report, p. 23.

[1] Edinburgh Medical Journal, November, 1913.

The dramatic onset of the illness in these cases rarely leaves any doubt as to the diagnosis; therefore an incision should first be made in the upper part of the abdomen to gain access to the perforation. This should be closed by invagination if possible, and where this is not feasible by an omental plug or stitching to a neighbouring viscus. If there has been much escape of gastric or duodenal content a tube may be inserted into the pelvis through a suprapubic stab-wound and the upper wound closed. If little escape has occurred the peritoneum may be left to look after itself and the abdomen may be completely closed. Such an operation takes no longer than that advocated by Mr. Corner, and the after-treatment of the case is much simpler—an important point where the patient is in a private house or at some distance from the medical man.

I am, Sir, yours faithfully,

Edinburgh, Jan. 12th, 1914. D. P. D. WILKIE.

ANTS AS TRANSMITTERS OF TROPICAL DISEASE.

To the Editor of THE LANCET.

SIR,—The annotation entitled "Ants as Transmitters of Tropical Disease," which appeared in THE LANCET of Jan. 10th, serves a useful purpose in directing attention to a matter which is possibly of very considerable importance, and which until recently had not received the attention it appears to merit. You kindly mention the suggestion I made in 1908 and refer to the interesting work of Dr. Bates on the mechanical transmission of B. typhosus and B. dysenteriæ by a species of large ant in the Canal Zone. I would like to mention that it was Dr. S. T. Darling who re-directed attention to this question, and that Messrs. Bates, Jacob, and Jennings carried out the necessary tests under his direction.

Dr. Darling's paper, which appeared in the Transactions of the Fifteenth International Congress on Hygiene and Demography, is entitled "The Part Played by Flies and other Insects in the Spread of Infectious Diseases in the Tropics, with Special Reference to Ants and to the Transmission of Tr. Hippicum by Musca Domestica."

I had hoped to carry out at Khartoum experiments on the lines of those conducted by Dr. Bates and his colleagues, but was unable to do so. At the same time I made one observation which is of some interest, and to which I think I once referred at a meeting of the now defunct Society for the Destruction of Vermin. A species of large ant in the Sudan has a great liking for urine. It haunts chamber-pots. This idiosyncrasy is not to be explained by a mere love of fluid, for if urine be allowed to dry in a vessel the ants are almost certainly to be found crawling over the dry uratic deposit which in the tropics so often results. I am inclined to think that urea has a special attraction for them, though no doubt liquid and moisture also entice them.

This being so, it is possible that in certain cases ants might transmit the Micrococcus melitensis in food such as milk or cheese. In the same way B. typhosus might be carried from the urine by these insects. It is not very likely that either of these accidents happens in nature, but it is worth while keeping the possibility in mind, for sometimes isolated sporadic cases of undulant fever and enteric fever crop up and are very difficult to explain. In any case, it is to be noted that urine and urinary deposits serve to attract a species of large ant which is very common in Khartoum, but the scientific name of which I have unfortunately forgotten. I am, Sir, yours faithfully,

ANDREW BALFOUR.

Wellcome Bureau of Scientific Research,
Wigmore-street, W., Jan. 13th, 1914.

THYROID SECRETION AND ANTITOXIN.

To the Editor of THE LANCET.

SIR,—In reference to my article entitled "The Relation of the Thyroid to Antitoxin," which appeared in THE LANCET of Dec. 27th, 1913, I am informed by Dr. A. T. MacConkey that he does not use potassium mercuric iodide as an antiseptic, and that as regards the sera supplied by the Lister Institute, any iodine present cannot be accounted for in this way. In the annotation upon the same subject, which appeared in the same issue, "the toxic effects induced in rabbits by injection of antitoxic serum," should read, "the toxic effects induced in rabbits by *feeding* with antitoxic serum."

I am, Sir, yours faithfully,

RUPERT FARRANT.

Queen Anne-street, Cavendish-square, W., Jan. 7th, 1914.

THE PATHOLOGY OF RHEUMATOID ARTHRITIS.

To the Editor of THE LANCET.

SIR,—I have read with much interest the letter on this subject contributed by Dr. P. W. Latham to THE LANCET of Jan. 10th. In the second column on p. 145 and on p. 146 he expresses his opinion that the presence in the blood and tissues of the "products of imperfect metabolism of muscular and other tissues" "imperfectly excreted" enable micro-organisms otherwise avirulent to become pathogenic, and so cause arthritis. My experience of fibrositis—and periarthritis and many conditions at present described as rheumatoid arthritis are forms of fibrositis—has led me to the belief that not only does imperfect elimination of waste matter enable pathogenic organisms to develop and become virulent, but that these materials are sufficiently toxic to be themselves a cause of fibrosis and fibrositis. I have dealt with this in some detail in a paper published in the Transactions of the Royal Society of Medicine (Balneological Section, April, 1913), entitled "Daily Habits in Civilised Life as Factors in the Causation of Fibrositis," and hope with your permission to present certain aspects of it to your readers at an early date. If the view thus expressed is correct, in all conditions of chronic arthritis and fibrositis and possibly in most diseases of middle and later life, the vitiation of the blood and tissues caused by imperfect elimination of waste products—a condition I have ventured to name "dyscatharsia"—is a very important, if not the most important, factor.

In recent years in the study of the seeds of disease too little attention has been paid to the soil, *especially to the soil of the adult, modified as* it necessarily is by the habits and environment of years.

---

[2] THE LANCET, August 1st, 1896.

I hope Dr. Latham will be able to publish at an early date his promised further contribution on this subject. I am, Sir, yours faithfully,

Llandrindod Wells, Jan. 13th, 1914. R. ACKERLEY.

DISLOCATION OF THE PROXIMAL PHALANX OF THE GREAT TOE.

To the Editor of THE LANCET.

SIR,—I was called a few days ago to a miner who had been caught by the trouser pocket by a revolving wheel and swung violently round the room. His injuries consisted of skin scratches in various parts and a dorsal dislocation (easily reduced) of the proximal phalanx of the great toe on one foot. At the time of the accident he was wearing the heavy boots common to miners.

The case is interesting in connexion with that mentioned by Dr. Henry Robinson in his letter in your columns last week and your previous annotation. I am, Sir, yours faithfully,

GEORGE F. RIGDEN, M.B., B.S. Lond., M.R.C.S., L.R.C.P.

Cinderford, Glos., Jan. 10th, 1914.

IMPROVEMENTS IN THE NAVAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—The recent alterations and improvements in the Naval Medical Service announced in your Service news have been long asked for.[1] I think it would have done more good to recruiting had better pay been given, particularly increased pay for higher qualifications—1s. a day for each extra qualification obtained within the first ten years of service, 2*s*. for each obtained in the next ten (to encourage officers to go through courses when they are becoming rusty), and 2*s*. 6*d*. for any obtained after 20 years. Executive officers who get higher qualifications are paid better—from 1*s*. 6*d*. to 4*s*.—as gunnery, torpedo, or navigating officers, although they get their education at the public expense.

I am, Sir, yours faithfully,

Jan. 10th, 1914. FLEET-SURGEON, R.N.

THE NATIONAL INSURANCE ACT: THE SURPLUS FUNDS.

To the Editor of THE LANCET.

SIR,—Reading in THE LANCET of Jan. 10th Mr. E. Nundy's letter, and your further comments, on the distribution of unallotted National Insurance funds, I venture to invite your readers to consider a suggestion which I have embodied in a letter to the Insurance Commissioners. It has struck me that part, at any rate, of the unallotted fund, after all doctors have been paid what is due to them, might well be retained as a reserve fund for doctors who have promptly gone to a midwife's assistance, when, owing to the poverty of the patient, there is a difficulty about the fee. The weekly wage of the insured person might be taken into consideration, for those who can afford it are generally found quite willing to pay.

The recent case of a patient's death after a *midwife had sent for several doctors, and the* coroner's remarks at the inquest, is still fresh in our memories, but no one, least of all the midwife, expects a doctor to do arduous work for nothing. Things have made strides since the days of my training, but it may not be out of place to remark here that on one occasion I sent for ten doctors in succession, with refusals from each one, to come to my assistance for a transverse presentation. Happily I had wisely done this early enough in labour that there was no immediate danger to my patient, and ultimately two women doctors arrived with chloroform. I did not blame the doctors then, nor do I do so now; it was midnight, a blizzard, and I, a stranger, calling them to the poorest of tenement houses. Only one or two touched upon the fee question; besides which, each one who refused did not know that nine others would do the same; and I have since known many who rise from their beds to do arduous work without much hope of monetary reward.

Reports of the Central Midwives Board penal cases show how many midwives are removed from the roll for failure to send for medical aid. But, whatever happens afterwards, the Board holds a midwife to be free of blame if, in obedience to the rules, she has called in a doctor on the first recognition of symptoms for which she is forced to send for medical assistance. A reserve fund for adequate payment of doctors when attending very poor cases would benefit both doctors on the panel and those who are not. It would benefit the midwife, who would not hesitate to get help early in labour, resulting in easier work for the doctor who comes to her assistance. It would benefit the poorest of insured patients by relieving them of the anxious worry of another fee to pay, leaving more for *nourishment, which, with freedom from* worry, might prevent loss of milk, to the benefit of the child. Lastly, it would benefit the State by preserving (who knows) a Prime Minister or a Poet Laureate, and thereby decreasing the infant mortality.—I am, Sir, yours faithfully,

JANET EWART STCLAIR,
Honorary Secretary, Fulham Association of Midwives.
Irene road, S.W., Jan. 10th, 1914.

CENTENARIANS.—The death is announced at the village of Newcastleton, Roxburghshire, of Mrs Helen Kerr in her 104th year.—Mrs. *Lambert has recently* celebrated her 100th birthday at Edmonton.

ROYAL LONDON OPHTHALMIC HOSPITAL.—The eighth annual dinner of past and present students will take place at the Imperial Restaurant, Regent-street, W, on Tuesday, Feb. 3rd, at 7 45 for 8 o'clock, Mr. G. A. Berry, LL D., F.R.C S Edin, in the chair. Each student is entitled to introduce two guests. Tickets (price 10*s* 6*d*. each, exclusive of wine) may be had on application to either of the honorary secretaries—Mr. Arnold Lawson, 12, Harley-street, W., or Mr. J. Herbert Parsons, 54, Queen Anne-street, W.

THE SOCIETY OF MEDICAL OFFICERS OF HEALTH: SCHOOL MEDICAL SERVICE GROUP.—*A general meeting* of the North-Western Branch of this body will be held in the Milton Hall, Deansgate, Manchester, on Saturday, Jan. 24th, at 2.30 P.M Important matters will be considered, such as the improvement of the status and remuneration of the service, consideration of security of tenure in relation to increase of salary, necessity of including public health work to relieve *the monotony* of medical inspection, and the advisability of forming a north-western branch group of the main group of the society.

---

[1] THE LANCET, Dec. 6th, 1913, p. 1649.

THE NATIONAL INSURANCE ACT.

THE MANCHESTER SYSTEM.

IN a recent report of the Medical Committee at Manchester upon the working of the National Insurance Acts for the quarter ending Sept. 29th, 1913, it was stated emphatically that the medical practitioners had carried out their work without friction so far as their patients were concerned, and that relations with pharmacists had been amicable under a serious strain. The same document, however, dwelt upon the inadequacy of the estimates of sickness and the consequent financial difficulty as affecting Manchester, and pointed out that this difficulty arose out of the provision of one fixed sum per head to defray the expense of medical attendance and drugs throughout the country. This flat rate assumed that sickness in Manchester and similar cities and towns would be the same in frequency of occurrence and in seriousness as in rural districts and health resorts, and as in Manchester a system of payment by attendance was adopted the soundness of the official estimate as applied to the health of such a population has been put to a practical test. The result shows up to the present that the money available is insufficient, and the sufferers are likely to include the medical practitioners, the pharmacists, and the Approved Societies, these last being able, to some extent, to do what the others cannot—namely, to recoup themselves in healthy areas for their losses where sickness is more prevalent. As a remedy for the difficulty, and in order to restrain any tendency on the part of the medical profession to respond unnecessarily to claims for their attendance, as well as to keep the number and cost of prescriptions as low as possible, the following conditions are proposed for the regulation of medical attendance and the provision of medicines at Manchester:—

1. The Panel Committee shall ascertain from the monthly accounts rendered by practitioners the average cost per patient in respect of the treatment given by each practitioner during each month, and may, if they so think desirable, take the general average cost per patient in respect of the treatment given to the whole of the patients within the area of the Insurance Committee for each monthly period as the basis upon which the amount to be credited to each practitioner shall be determined, provided that, if the Panel Committee so think desirable, such amount shall not exceed in the aggregate a sum of £800 per annum.

2. The Panel Committee shall ascertain from the monthly accounts rendered by (*a*) practitioners and (*b*) chemists and contractors undertaking to supply drugs and appliances, the average cost per patient, the average value per prescription, and the average number of prescriptions per patient in respect of the prescriptions given by each practitioner during each month, and may, if they so think desirable, take the general average cost per patient, the general average value per prescription, and the general average number of prescriptions per patients (or any of them) in respect of the prescriptions given to the whole of the patients treated within the area of the Insurance Committee for each monthly period as the basis upon which deductions to be made from the amounts payable to practitioners shall be determined.

Our Manchester correspondent (see p. 205) reports willingness among medical men to agree to these terms, which not only mean the cutting down of every income derived from panel work to £800 or less, but impose a limit on the free choice of a medical attendant, which has been claimed on behalf of patients by the medical profession.

THE QUESTION OF DRUGGISTS' CHARGES AT SALFORD.

At Salford the Insurance Committee has had the same difficulty as the Manchester Insurance Committee in endeavouring to meet the cost of prescriptions under a system of payment by attendance. A letter to the Insurance Commissioners stating that the sum at the disposal of the Committee only enabled it to pay 70 per cent. of the chemists' charges brought a reply to the effect that the deficiency seemed to be due to the number, not the nature, of the prescriptions given, and that if this state of things was traceable to the special arrangements made in Salford the medical profession and the druggists must arrange the matter between them before the Commissioners could approve a continuance of the special arrangements referred to. A proposal made on the basis of an agreement arrived at between the medical men and the pharmacists failed later to secure the approval of the Commissioners as not coming within the Regulations, and the situation appears now to be that the pharmacists sign contracts for another year on the understanding that a scheme in substance the same as that mentioned shall be worked under Rules 39 and 40 of the new Regulations, and presumably the strict exercise of the powers given by these two rules to panel committees will to some extent have the effect desired. It is not suggested that the patients at Manchester or Salford have had anything to complain of. It is evident they have n expressed dissatisfaction at excess of medical atten ances or medicines, and it is yet to be seen wheth the proposed curtailment of both will meet wi their approval. It must be said at the same tim that the figures recently published at Salford sho a deficit even more formidable than that referred above. The sum available to Nov. 14th, 1913, wa £6833, to meet claims amounting to £10,000—i.e very little more than two-thirds. It may also b added that hard things have been said by members of the Salford Insurance Committee against some of the medical men alleged to have prescribed excessively. Their conduct has been contrasted with that of the majority of their colleagues, and the possibility of obtaining their removal from the panel has been distinctly hinted at.

LEICESTER INSURANCE COMMITTEE: THE UNALLOTTED FUNDS.

The Leicester Insurance Committee has a balance in hand of £1500 available for medical benefit, and the Medical Subcommittee has recommended its distribution between the practitioners on the panel in accordance with the number of patients on their lists. At a recent meeting of the committee the matter was referred back for further consideration after a member of the committee, Mr. T. F. Richards, had advanced th opinion that the distribution proposed would b "a bonus for something the doctors had not done," and recommended the expenditure of the money in sanatorium benefit. The injustice and mis understanding involved in such a contention cannot be too emphatically pointed out. Whate may be the legal position with regard to surpl medical funds, they were contributed by employe and employed under legal compulsion as paymen to the medical profession for medical benefit. Ever insured person, well or ill, has had in return the promise of the money in question attendance as his right throughout. The money was promised to the medical men serving on the panels, and it was agreed by the medical profession to accept a rate of payment which would have been inadequate if every insured person was to be a patient requiring medical attendance, on the ground that many would not, in fact, need medical aid, and that their money would go towards paying for those who did.

A MEDICAL INSTITUTE REJECTED BY THE COMMISSIONERS.

The Boston Medical Institute appears to be an organisation established by the local Approved Societies of the district in order to provide medical attendance for persons not coming under the National Insurance Acts, but will accept transference to it of insured persons willing to be so transferred. The Insurance Commissioners have refused, however, to accept the Boston Medical Institute for recognition under the Insurance Acts on the ground that it was not in existence when the Insurance Act, 1911, was passed, and the medical men practising upon the panel within the district from which the institute draws its members are to be congratulated. Working men will in time recognise generally the badness of the policy of sacrificing the medical attendance provided by the Insurance Act in favour of the medical attendance provided by such institutes.

BOROUGH OF LAMBETH INSURANCE PRACTITIONERS' ASSOCIATION.

At a meeting of the executive committee of this association, held on Jan. 6th, at Stockwell, Mr. J. Fleming in the chair, the proposed action of Mr. Nundy against the London Insurance Committee was considered and discussed. The following resolution was passed unanimously:—

> That this meeting of the Borough of Lambeth Insurance Practitioners' Association executive committee desires most strongly to dissociate itself with the proposed legal action which Mr. Edward Nundy, of Tooting, contemplates entering nto against the London Insurance Committee. This meeting considers such action detrimental to prospects of amicable settlement and inadvisable, as likely to lead to many unforeseen complications.

The secretary was instructed to forward copies of this resolution to Mr. J. A. Dawes, M.P., chairman of the London Insurance Committee, Mr. Thomas Batey, the Chancellor of the Exchequer, and the Insurance Commissioners, also to write to Mr. Nundy expressing the views of the meeting. The meeting considered that if any legal action became necessary the proper body to undertake it was the Panel Committee.

THE TUBERCULOSIS DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.—Owing
new department the following
have been appointed—namely,
Candler, and Dr. A. S. McNalty.

LIVERPOOL HEALTH DEPARTMENTS. — Major C. E. Norton, of the Local Government Board, held an inquiry on Jan. 13th at Liverpool into the application by the Liverpool city council for power to borrow money for the erection of a building to accommodate the departments of the city bacteriologist and city analyst. It is further proposed to make provision in the new building for the school of hygiene of the University of Liverpool.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the First Professional Examination of the Conjoint Board, held on Dec. 30th and 31st and Jan. 1st and 2nd the following candidates were approved in the under-mentioned subjects:—

Hospital.
Chemistry.—Richard Ambler, Middlesex Hospital; Hussein Amin, Cairo and St. Bartholomew's Hospital; Herbert Claude Apperly,
South-Western Polytec
Liverpool University;
tute; Edward Francis
Houghton, Manchest
University and Guy
Birmingham University; Charles Farrell Rainer, London Hospital.

Charles Woodroffe, Guy's Hospital.

At the Second Professional Examination in Anatomy and Physiology held on Jan 1st, 2nd, 5th, and 6th, 75 candidates presented themselves, of whom 42 were approved and 33 were rejected. The following are the names and schools of the successful candidates:—

Willoughby Oxford Universities;
Edward University; Frank
Macdonal and King's College;
Charles H tholomew's Hospital;
Hugh Sta rthur Bulleid, Guy's Hospital; Alan Andreas Cockayne, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Walter Tyrrell Cooper, Charing Cross Hospital and King's College; Marcelline de Costa, Ceylon Medical College and University College; Alexander John D'Souza, L.M. & S. Madras
pital; William Felix Ebe
Charles Arthur Lovatt
William Farquharson,
Collingwood Fenwick,
Fonseka, Ceylon Medi
Maurice Rolfe Vickers
Tyndall Garraway, Lon
Gokharkar, L.M. & S. B
Hospital; Christopher

W. Dawson and Sons, Lond.; Messrs. Duncan, Flockhart, and Co., Lond.; Dorland Agency, Lond.; Dr. H. G. Drake-Brockman, Middlesbrough.

E.—Dr. W. d'Este Emery, Lond.; Dr. C. T. Ewart, Woodford Bridge; Ellis Health Food Co., Stockport; Messrs. Eyre and Spottiswoode, Lond.

F.—Dr. S. Felce, Burgess Hill; Messrs. Feret et Fils, Bordeaux; Dr. R. Speirs Fullarton, Glasgow; Factories, Chief Inspector of, Lond.

G.—Mr. E. W. Hey Groves, Clifton; Dr. A. Graham-Stewart, Margate; Dr. M. Greenwood, Lond.; Dr. J. Dundas Grant, Lond.; Gloucestershire Royal Infirmary, Gloucester, Secretary of; Guest Hospital, Dudley, Secretary of; General Infirmary, Macclesfield, Chairman of; Dr. H. M. Gurney, Newcastle-on-Tyne; G. W. P. C.; Messrs. W. and A. Gilbey, Lond.; Mrs. Gillies, Easdale; Professor T. Wardrop Griffith, Leeds.

H.—Miss E. Howse, Lond.; Mr. H. G. A. Harding, Sydney; Dr. John Haddon, Denholm; Dr. David Heron, Lond.; Harrogate Infirmary, Secretary of; Harley Institute, Lond., Principal of; Messrs. Hunt, Roope, Teague, and Co., Lond.; Mr. Wm. Heinemann, Lond.; Messrs. Harrison and Sons, Lond.; Dr. C. M. Hinds Howell, Lond.

J.—Mr. J. G. Jackson, Abergwynfi; Dr. G. R. Jeffrey, York; Dr. O. Jennings, Lond.; J. W. J. W.

K.—Messrs. King Bros., Hastings; Messrs. H. S. King and Co., Lond.; Mrs. Kayser, Fleet; [illegible]

L.—[illegible] Association, Lond., Secretary of; Liverpool Corporation, Clerk to the; Dr. R. W. Leftwich, Lond.; Liverpool Stanley Hospital, Hon. Secretary of; Messrs. Lee and Nightingale, Liverpool; Dr. S. F. Linton, Scarborough; Mr. H. K. Lewis, Lond.; Liverpool University, Sub-Librarian of; Mr. D. L. Luksumanaswami, Chamarajapet; London School of Massage, Secretary of; Dr. Arthur P. Luff, Lond.; Local Government Board for Scotland, Edinburgh; Local Government Board, Lond., Medical Officer to.

M.—Dr. [illegible] *Mornin*[illegible] of; Dr [illegible] John R. McGill, Milwaukee; Dr. W. H. Mills, Lond.; Messrs. C. Mitchell and Co., Lond.; Messrs. Masson et Cie, Paris; Mr. J. F. Mackenzie, Edinburgh; Maltine Manufacturing Co., Lond.; Dr. Murray, Lond.; Dr. Macdonald, Edinburgh; Manchester [illegible] Mr. G. [illegible] Manches[illegible]tee, Secretary of; Messrs. Z. P. Maruya and Co., Tokyo; Mr. T. B. Marshall, Lechdale; Mr. G. Macdonald, Edinburgh; Dr. E. Mecredy, Lond.; Mrs. Maxwell, Brighton; Messrs. May and Baker, Lond.

N.—Dr. David Newman, Glasgow; National Association for the Prevention of Infant Mortality, Lond., Secretary of; *The Newspaper Owner and World*, Lond.; Newcastle-upon-Tyne City Asylum, Clerk to; Dr. H. C. Nott, Lower Mitcham; Norfolk Education Committee, Norwich, Secretary of.

O.—*Dr. H. O'Neill, Belfast*; Ogston Motor Co., Acton; Sir Thomas Oliver, Newcastle-on-Tyne.

P.—Dr. Owen Paget, Fremantle; Mr. W. G. Porter, Edinburgh; Mr. J. H. Parsons, Lond.; Sir R. Douglas Powell, Bart., Lond.; Mr. J. J. Pickles, Leeds; Dr. P. N. Panton, Lond.; Pharmaceutical Society of Great Britain, Lond., Secretary of.

R.—Royal Institution of Great Britain, Lond.; Dr. George Rigden, Cinderford; Royal Institute of Public Health, Lond., Secretary of; Royal Meteorological Society, Lond.; Royal Microscopical Society, Lond., Secretaries of; Royal Society, Lond., Assistant Secretary of; Royal Isle of Wight County *Hospital*, Ryde, Secretary of; Royal Portsmouth Hospital, Secretary of; Messrs. Reynell and Sons, Lond.; Rochdale Infirmary, Secretary of; Mr. E. H. Roberts, Lond.; Royal Albert Edward Infirmary and Dispensary, Wigan, Secretary of; Rochester and Chatham *Printing* Co., Rochester; Mr. R. Râm, Glasgow; Royal Surrey County Hospital, Guildford, Secretary of; Mr. H. Rainsford, Reading; The Royal Gwent Hospital, Newport, Secretary of.

S.—Mr. A. E. Smith, Reading; Scottish Poor-Law Medical Officers' Association, Glasgow; Miss St. Clair, Lond.; Messrs. G. Street and Co., Lond.; Dr. René Sand, Brussels; Dr. Edward W. H. Shenton, Lond.; Scarborough Hospital and Dispensary, Hon. Secretary of; St. Mary's Hospital for Women and Children, Lond., Secretary of; Somerset and Bath Asylum, [illegible] Secretary of; [illegible] General and Eye [illegible] Secretary of; The J. C. [illegible] Co., [illegible]; Messrs. Sackville, Barton, and Co., Lond.; Mr. A. Stenhouse, Glasgow; Mr. F. W. Sears, Lond.; Mr. J. A. Southern, Derby; Dr. S. Seekings, Lond.; Dr. J. Sequeira, Lond.; *The Sunday at Home*, Lond., Editor of; Société Internationale de Chirurgie, Brussels, Secretary of; Dr. Edmund J. Spriggs, Banff.

T.—Dr. Leslie Thorne Thorne, Lond.; T. S.; Throat Hospital, Lond. Secretary of; Dr. P. L. Townley, Gayndah.

U.—University of London Graduates' Association, Lond., Hon. General Secretary of; University of London, Principal of; Messrs. Urban and Schwarzenberg, Berlin

V.—Dr. Ralph Vincent, Lond.; Messrs. J. W. Vickers and Co., Lond.; Victoria Hospital, Burnley, Secretary to; Dr. T. G. Vawdrey, Plymouth.

W.—West London Medico-Chirurgical Society, Lond., Senior Secretary of; Mr. Josef Winkler, Vienna; Mr. D. P. D. Wilkie, [illegible] West-End [illegible]nd.; Mrs. [illegible]nghouse [illegible]nd.; Mr. [illegible] Watson-[illegible]rs. W. J. Wilcox and Co., Lond.; Messrs. A. Wander, Lond.; Messrs. A. J. Wilson, Lond.; Dr. G. Whitehead, Dukinfield; W. K.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. J. P. Aiken, *Camlough*; Dr. J. Allen, Lond.; Ashton-under-Lyne Union, Clerk to the; Messrs. T. and M. Armstrong, Lond.; Mr. E. F. Ackery, Lond.; Dr. J. G. Andrew, Glasgow; A. G.; A. W., Liverpool.

An Address

ON THE

PATHOLOGY OF SYPHILIS, ESPECIALLY IN ITS BEARING ON TREATMENT.

Delivered before the Medical Society of London on Jan. 12th, 1914,

By W. d'ESTE EMERY, M.D., B.Sc. Lond.,

DIRECTOR OF THE LABORATORIES AND LECTURER ON PATHOLOGY AND BACTERIOLOGY, KING'S COLLEGE HOSPITAL, LONDON

Mr. President and Gentlemen,—Syphilis is perhaps of all others the most interesting disease at the present time. For centuries past it has been, from its commonness and from its serious nature, a disease of the utmost importance; but it has been a mystery, and a mystery which the passage of time has done but little to elucidate. Indeed, if we compare our knowledge of syphilis of ten years ago with that of the most educated physicians of a period 50 years after the discovery of the Americas and the subsequent spread of the disease over the civilised world, we can find comparatively little that has been added of fundamental importance. The clinical manifestations of the disease had been more carefully studied, and some knowledge—useless and not altogether accurate—had been gained as to the morbid anatomy of its lesions; the use of mercury was perhaps more scientific, and another remedy, iodide of potassium, had been introduced—the latter perhaps not an unmixed benefit; and, most important of all, the syphilitic nature of two diseases of enormous importance, themselves of comparatively recent discovery, had been firmly established. I allude, of course, to tabes and general paralysis.

ADVANCES IN KNOWLEDGE OF SYPHILIS.

What a change at the present day! Thanks to the researches of Schaudinn, Metchnikoff, Wassermann, Ehrlich, and others, we have now as good a knowledge of syphilis as of any other disease, except perhaps malaria.

Let me recapitulate briefly what I mean by saying we understand an infective disease. I mean that we know the organism which causes it, so that we can recognise it with certainty, and make use of its demonstration in diagnosis. Further, we must know how this parasite behaves outside the body, its vitality, and its intermediate hosts, if any; we must know how it gains access to the body, and what causes facilitate its invasion; when arrived in the body, we must know the regions it attacks, and the methods by which it is disseminated therein, should such dissemination occur; what toxins it produces, and how they injure the tissues and, still more important, alter the normal physiological processes, and thus give rise to the symptoms of the disease. We must also understand those elaborate and complicated processes which all micro-organisms set up in the living body, and which we refer to as the reactions of immunity—that is to say, we must understand how the body defends itself against the invaders, and how natural recovery, should it occur, is effected. We must have a test which will enable us to diagnose the disease early, or when clinical symptoms are ambiguous. We must have a cure, which if properly applied is a practically certain one; and, lastly, we must have some means of telling when a patient is actually cured and the disease is dead and not merely sleeping.

Now I do not say that there are no gaps, and those of great importance, in our knowledge of syphilis, but I think I can say that, whereas ten years ago our knowledge was almost all gaps, now the unexplored fields loom very small beside the territory which has been fully surveyed and is definitely known. I think we may say with Shakespeare, "And is not this an honourable prize, a gallant spoil?" and reply with him, "It is a conquest for a king to boast of."

I have attempted to-night, very ambitiously, to outline to you our know [illegible] from the point of view of [illegible] more especially the beari [illegible] treatment of the disease. This is a large subject, and with your permission I will plunge at once into the heart of the matter.

THE TREPONEMA PALLIDUM.

As regards the cause of syphilis, there is at the present time no doubt that the spirochæta pallida or treponema pallidum of Schaudinn is the actual *materies morbi*. It fulfils all Koch's postulates; it is present (though sometimes in scanty numbers and not easy to find) in all stages of the disease; it can be cultivated outside the body and the cultures kept going for many generations, so that we can be certain that no trace of the original material is present; and these cultures will convey the infection to the lower animals and in all probability to man. It has, as far as we know, no independent existence outside the body, and under such conditions rapidly dies; infection, therefore, is almost always direct, and the conveyance of the virus by fomites only possible for short periods of time. It has no intermediate host and is, under natural conditions, an exciter of disease in Homo sapiens only. I do not think I need take up your time by discussing its morphology, which is now so well known. And as regards its life-history, I need only say that I for one am unconvinced by those who claim to have demonstrated a complicated life-cycle. The fact that the organism exists as a spirochæte in lesions in all phases of the disease, from the primary chancre and even from an earlier stage (Levaditi and Yamanouchi), to the last stage of tabes and general paralysis, that it can be cultivated for many generations, during which (except for a few occasional spherical bodies which are probably involution forms) it remains a spirochæte, shows that there is no necessity for assuming any other form in its life-history. However, the question is entirely one for demonstration, and at present we must be content with regarding the alleged life-cycle as non-proven. I need hardly remind you that some still regard the organism as a bacterium, and that if this is the case the existence of a complicated life-history is impossible.

THE EARLY STAGES OF INFECTION.

Let us now trace out, as well as we can, what takes place when a person is infected with syphilis. There is, to begin with, a period of three or four weeks during which there are no obvious effects whatever, but in which the spirochætes are known to be multiplying in the epithelial and subepithelial tissues, and causing in them a very slight degree of the histological changes characteristic of syphilis. After a time the picture changes suddenly; there is sudden outburst of activity in the parasites; they multiply rapidly and liberate their toxins, which and especially cell degeneration, are present. According to Noguchi the reaction obtained with his true antigen may be taken as a fair proof of the defensive reaction, whilst the ordinary Wassermann reaction is some measure of the extent of the syphilitic processes. It is not, however, exactly quantitative, since a patient in whom there is a strong Wassermann reaction may show comparatively slight histological changes in the tissues, and *vice versâ;* but I think that in general terms the potency of the Wassermann reaction in any particular patient is roughly proportional to the extent of his lesions, diminishing as they are cured and becoming more marked as they increase. You will notice that the Wassermann reaction usually appears about the middle or end of the primary stage—that is, about the time that the tissue cells and lymphocytes have had time to collect round the colony of organisms and to undergo degeneration, and that it becomes much stronger during the secondary period, when the histological changes are so much more widespread.

A very difficult question arises in regard to the occasional disappearance of the Wassermann reaction in later tertiary syphilis in spite of active syphilitic lesions. This is, I think, especially common in congenital syphilis, in that it is not uncommon to find patients of middle age with marked symptoms of congenital syphilis but with no Wassermann reaction or with a very weak one. The explanations which may be suggested are purely theoretical. It is possible, for example, that in these long-standing cases the body and the affected cells may have had time to adapt their metabolism to the new conditions, and that though the toxin may compel them to suffer degeneration this may not take precisely the same form as in the person who has been but recently infected. Or perhaps the body may develop some method of dealing with the products of cell degeneration which in the earlier stages of syphilis circulate for long periods in the blood. On the whole I think this is the more probable explanation. We know from the researches of Abderhalden and others that the body has many methods of dealing with foreign substances, and it is quite in accordance with experience in other conditions that it should evolve some way of destroying or absorbing the Wassermann substance when present in the blood for long periods of time.

In some cases, perhaps in all, the tissues of the patients in these advanced cases may be made to produce the Wassermann substance by the administration of salvarsan, as in the so-called provocative reaction. Salvarsan, as I shall show later, kills numerous spirochætes, thus releasing much endotoxin and causing a sudden outburst of cell degeneration. If the explanation of the absence of the Wassermann reaction I have suggested is correct, this would indicate that the mechanism which can deal with a small amount of the Wassermann substance is unable to cope with a large quantity. It is interesting to notice that these old cases of syphilis which give no Wassermann reaction usually give a marked luetin reaction, and this is especially the case after they have been treated with salvarsan or mercury.

The important practical point to remember is that the presence of a Wassermann reaction indicates the presence of active disease. Its absence, on the other hand, does not necessarily imply complete cure, except, perhaps, under conditions which I shall discuss subsequently.

THE ACTION OF DRUGS.

I pass on to deal with the action of drugs. Mercury and salvarsan are direct spirillicide agents, exerting a direct action on the organisms comparable to that of quinine on the malaria parasite. In the case of salvarsan there is direct *in vitro* evidence of this, but in the case of mercury the proof is indirect, though not less convincing. The effect of either of these drugs is to cause a more or less rapid destruction of the parasites, with liberation of their protein molecules. Hence, there is a very important indirect result—namely, a sudden increase in, or production of, the negative phase, and a subsequent increase in the production of antibodies. The latter phenomenon is, I think, responsible for no small part of the curative effect of the agents in question; they kill some of the spirochætes, and these killed bacteria then act as a vaccine, causing a production of antibodies which carries their curative action still further. How much of the beneficial effect of these drugs is due to their direct chemical action and how much to the secondary vaccine-like effect it is impossible to say.

You will have noticed that I speak of the solution of the spirochætes as a necessary condition for the production of antibodies and also for the development of toxic symptoms. This is the case with many protozoa, which when they inhabit the blood cause no symptoms unless they are first killed and dissolved, or unless, as in the case of malaria, t enter and destroy the red corpuscles; and in t case they cause symptoms only when the corpuscles themselves are dissolved. Trypanc mata can flourish in large numbers in the bloo a guinea-pig, and cause no impairment of he whatever; but when a large dose is injected s of the animals may die, and in these no trypa somes can be found in the blood or internal org having doubtless been dissolved by the trypanoci substances in the blood (Wolff-Eisner). This is course, an example of the general law *corpora n agunt nisi soluta,* and it is a principle to bear c stantly in mind in dealing with the action these drugs.

The Herxheimer and other Reactions.

Take, for instance, the very important ph nomenon known as the Herxheimer reaction. is well known, the first effect of mercury, especial if given in a form in which the system is rapid brought under its influence, is in many cases t cause a marked intensification of the rash, or there be no rash present one may rapidly form; i addition to this, tonsillitis may appear or may b made worse, syphilitic headache, iritis, &c., ma also be produced, or if present may be aggravate The same thing, even more marked, may be see after an intravenous injection of salvarsan; her a very large amount of an active spirillicide agen is thrown into the blood at once, many spirochæte are destroyed in a few hours or minutes, and muc endotoxin is set free; the symptoms are often mad decidedly worse for a few hours or a day or so and it is always well to warn the patients of the fact. A similar phenomenon may be seen in the primary stage; the day after the injection the chancre may swell and become exquisitely painful and even bleed profusely; and in this or in the secondary stage there may be high fever, which is certainly not due altogether to the presence of dead bacteria in the water, since it may occur when a dose of neosalvarsan is given in a small amount

(5 c.c. or less) of recently distilled water, as I have observed several times of late.

All these modifications of the Herxheimer reaction are due to the spirillicide action of the drugs in question, the dead organisms either undergoing autolysis or being dissolved by the spirillolytic substances in the blood, in either case with the formation of soluble substances which cause a reaction when they act on the hypersensitive tissues in the neighbourhood.

The iodides have no such action, so that it is sometimes recommended that we shall treat cases showing marked affections of the mucous membranes, such as laryngitis or tonsillitis, with these agents rather than with mercury or salvarsan. This, however, is a mistake, for the iodides have very little, if any, spirillicidal action, and relieve the symptoms rather than cure the disease. There is more reason for the use of iodides at the commencement of the treatment of diseases such as iritis and meningitis, in which a temporary flare-up of the symptoms may cause severe damage to the delicate tissues in the neighbourhood, but they must be followed by mercury or accompanied by small doses of that drug. The iodides, I may say, appear to act rather as an antitoxin than as a germicidal agent.

There are two other effects which may be produced by the action of mercury or salvarsan. The provocative reaction I have alluded to already, and have explained how it is caused by the destruction of organisms, the liberation of their toxin, and the consequent increased degeneration in the granulomata, with production of the Wassermann substance. The other effect is this: it may happen that the luetin reaction is absent in a late stage of the disease, and when this happens it can usually be made to appear by the exhibition of mercury or salvarsan. This is caused in a manner exactly analogous; the dead protoplasm set free by the destruction of the spirochætes sensitises the tissues to such an extent that they react to the same antigen in the form of luetin.

Disappearance of Wassermann Reaction in Relation to Cure.

When a patient has been vigorously treated with mercury the strength of the Wassermann reaction, as I have just remarked, tends to fall off, and this process continues until it disappears altogether. The negative Wassermann reaction at this stage depends on the absence of cell degeneration, and
ot prove that the spirochætes
treatment is stopped too soon
reappears, feebly at first, but
ongly, as the few spirochætes
hat have escaped destruction awaken into activity.
This raises a most important problem: having
emoved the Wassermann reaction by mercury, how
ong are we to wait before its non-reappearance
enotes the cure of the disease? In my own
xperience it usually comes back in three months,
ut may often be delayed for six. Occasionally it
nay be delayed much longer, and I have once known
to reappear a year after the cessation of treat-
ent. I am under the impression that this may be
garded as a safe limit.

THE TERTIARY STAGE.

When I come to deal with the tertiary stage, or
age of gumma formation, I must admit that I am
considerable difficulty in finding a complete and
mple explanation of the facts. The immunity
actions are now complex. The spirochætes are now rarely found in the blood, and are indeed present in but small numbers in the tissues; I think we may take this as indicating a blood immunity to the parasite. The spirillicide powers of the blood have come back to normal, or may indeed be increased. But the tissues are still sensitive. This is shown, amongst other things, by the effect of luetin, as applied in the Noguchi test: the reaction is almost always positive, frequently strongly so, so that the injection of the dead spirochætes may be followed by the formation of a pustule which breaks down and leaves an induration which may last some weeks. This does not mark a condition of immunity or of hyperimmunity as McIntosh and Fildes have recently suggested, nor, I think, does it indicate a great degree of hypersensitiveness. I look upon the condition as marking a gradual return to normal, a condition which it may reach if the disease dies out and all the spirochætes disappear.

Consider for a moment the nature of the histological changes which occur during an attack of syphilis. The first, the chancre, consists mainly of granulation tissue: there are cell proliferation and lymphocytic invasion, but there is but little of the dilatation of vessels and of the changes which are characteristic of acute inflammation. This is the reaction of the tissues when they are but slightly sensitive. But the nature of the earliest secondary lesions is quite different; here the changes, vascular and otherwise, of acute inflammation predominate, infiltration being entirely absent or but slightly marked, and these appearances I regard as indicating the reaction of the highly sensitive tissues. If we now trace the alteration of the lesions from this stage forward we find that we can construct a series—the papular syphilide, the follicular syphilide, rupia, and gumma—in which the acute inflammatory element gradually diminishes and granuloma formation becomes more and more marked, and the lesions which are formed come to resemble in their essential characteristic the chancre.

I must at this point remark that the fact that a syphilitic patient cannot be reinoculated with the disease does not indicate that he is, in the ordinary sense of the word, immune thereto. The fact is that (according to Finger, Wolff-Eisner, and others) he can be reinoculated, but that the resulting lesion matures rapidly into a small papule and the disease goes no further. This is, of course, due to the hypersensitiveness of the tissues; the defensive substances are more readily mobilised in a syphilitic patient than in a normal person, the period of incubation is shorter, antibodies or other defensive substances are soon on the spot in sufficient numbers to abort the further development of the spirochætes, and nothing but a small papule results. When the disease is completely cured it is completely reinoculable, the tissues having regained their former degree of sensitiveness; and I regard the tertiary stage as being an approach to this condition.

But I think there is another possibility which has to be considered, and that is that all this time the spirochæte is gradually altering in response to its changed environment, as we know may occur in better known bacterial infections. I have not time to go into this question at present, but it is one that must not be lost sight of as possibly playing a very important part in the pathology of the disease. I shall refer to it briefly subsequently.

evidence in favour of the supposition by a consideration of the observed fact that an alternation of mercury and salvarsan is more efficacious than either remedy alone. A spirochæte may gradually acquire tolerance to either drug when submitted to its action for long periods of time, but when exposed for a short time to arsenic and then to mercury it is quite in accordance with general biological facts that it should acquire tolerance for neither. And I believe late cases of syphilis are best treated in this way, with perhaps occasional periods of iodides.

Parasyphilitic Infections.

Now as to the alleged incurability of the parasyphilitic affections. I think here the issue has been confused by the fact that the patient who has had some of the important portions of his nervous system destroyed will not be clinically cured after the syphilis has been entirely eradicated; unless other portions of the nervous system can take up the functions of the destroyed parts he will be little better off than before, with this difference, that the disease will not progress. And that such a result can be accomplished with mercury alone, as Hayes has shown, I sincerely believe. But the question has entered on a new phase by the introduction of salvarsan and by the newer method of giving it introduced by Swift and Ellis. Even with the old method many cases can be brought to a standstill after a few injections, and in a few cure in the sense in which I have used the term has been obtained.

The new method of giving salvarsan in these cases is very interesting. Its theory is founded on the fact that the cerebro-spinal fluid acts as the lymph for the cerebro-spinal system, and that it forms a system of its own devoid of any direct connexion with the blood or lymphatic systems generally. Thus but few drugs which are injected into the blood or taken by the mouth are excreted by the choroid plexuses into the cerebro-spinal fluid and thus brought into contact with the nerve elements themselves. To remedy this Swift has proposed to inject the curative material directly into the cerebro-spinal fluid by lumbar puncture. The curative material in question consists, in his opinion, of antibodies which circulate in the blood after an injection of salvarsan. He gives an injection of that drug or of neosalvarsan, waits for an hour (after which time, he thinks, there is a large amount of antibody in the blood), bleeds the patient, allows the blood to clot, collects the serum, and injects it, after heating it to 60° C. to destroy the complement and diluting it with normal saline solution, into the spinal canal. I believe as a matter of fact that the theory is not a correct one, and that the serum owes its activity to the presence of minute traces of salvarsan. It seems quite impossible for large amounts of antibodies to be developed in so short a space of time.

In any case the results are very striking. I have already applied this method in three cases, one of general paralysis and two of tabes, with very excellent results. The paralytic patient's mental condition has improved in a very striking manner after a single injection, and his physical condition is also much better. The cases of tabes have also improved in a very gratifying manner, especially in regard to the practical complete loss of the lightning pains. In one case (a patient of Dr. H. W. A. Cowan) the light reflex, which had been absent for some has completely returned; in the other the light reflex is now normal, but there is some difference of opinion as to its absence previously, though, according to Sir David Ferrier and the house physician at King's College Hospital, this was actually the case. In all these cases there has been a diminution in the number of lymphocytes and the amount of globulin in the cerebro-spinal fluid. I do not for a moment claim that these patients are cured, but certainly the results are most encouraging. I think we must modify very considerably the statement that the parasyphilides are incurable. Allowing for the fact that they are examples of these late cases of syphilis in which the spirochætes are probably arsenic- and mercury-fast, and that they occur in a region which is not easily reached by drugs, I do not think they are less curable than we have any right to expect.

THE PROOF OF CURE.

Lastly, as to the proof of cure. The one and only certain proof of this happy consummation is the possibility of reinfecting the patient; this shows that his tissues have returned to their normal degree of sensitiveness, which cannot happen if there are spirochætes still in the body. This test is, of course, impracticable, and we must look about for something else. Whether the luetin reaction will help us in the future is as yet unknown, and at the present time we have to fall back on the Wassermann reaction. Under what circumstances does a negative reaction indicate cure?

To begin with, it is quite useless to draw any inference from its absence unless we know that it has been present comparatively recently. If we do not remember this we may find that we are dealing with one of the cases in which it has spontaneously disappeared in the tertiary stages, as I have already described, whilst the disease is still active. Then we must remember the effect of treatment; mercury and salvarsan will remove the reaction without necessarily curing the disease, the negative phase (if I may use the expression) lasting for so long a time as a year. Taking these facts into consideration, I think we may deduce this as a working rule: if in a patient whom we know to have had a Wassermann reaction we find it remains absent for a year after the cessation of treatment, we may assume with a high degree of probability that he is completely and radically cured, and I think we shall very seldom be mistaken. If we want a higher degree of certainty still, we may give an injection of salvarsan and see if the reaction reappears, and if it does not do so I believe the chain of evidence is complete.

Donations and Bequests.—By the will of the late Mr. John Hogg, of Belfast, the testator among other bequests left £5000 to the Royal Victoria Hospital, Belfast, £2000 to the Forster Green Hospital, Belfast, and £1000 each to the Ulster Hospital for Women and Children, the Hospital for Sick Children, Belfast, the Samaritan Hospital, Belfast, the Ulster Eye, Ear, and Throat Hospital, the Society for Providing Nurses for the Sick Poor, and the Ulster Institution for the Deaf, Dumb, and Blind.—The late Miss Amanda Hinchliffe, of Southport, has left by will £4000 to the Royal Halifax Infirmary, £1000 to the Bath Hospital at Harrogate and £500 to the North of England Children's Sanatorium.—The governors of the Hampstead and North-West London Hospital have received a donation of £1000 from Mr. H Gosschalk to name a bed in memory of his wife.—The *Referee* Children's Fund has sent £1000 to the Queen's Hospital for Children, Hackney, for its seaside branch at Bexhill.

DOSAGE:

SOME SUGGESTED AMENDMENTS IN THE MANNER OF STATING THE DOSES OF MEDICINES IN THE BRITISH PHARMACOPŒIA.

BY C. O. HAWTHORNE, M.D. GLASG.,
PHYSICIAN TO THE NORTH-WEST LONDON AND ROYAL WATERLOO HOSPITALS; FORMERLY LECTURER ON MATERIA MEDICA AND THERAPEUTICS, QUEEN MARGARET COLLEGE, UNIVERSITY OF GLASGOW.

THE presentation in the British Pharmacopœia of official doses of all medicines used for internal administration has one practical advantage—it forms for the public an additional safeguard against possible error. In the absence of such doses the dispenser has no authorised avenue through which he may approach the physician to seek the confirmation or correction of a dose which *primâ facie* ppears to be excessive. As safety in the framing nd *dispensing of prescriptions is of large public* nterest, it is not unreasonable that the national harmacopœia should provide machinery by which n accidental error on the part of the prescriber ay be checked and remedied. This is the one aluable function which the pharmacopœial doses ischarge. They put the dispenser in a position to ecure the correction of an excessive or dangerous ose due to a miscalculation or slip of the pen ommitted *accidentally by the* prescriber. In this ay they promote the safety of the public, and ence are capable of defence on the broad ground f the general interest.

There is, however, something to be said on the ther side. The creation of an official dosage is ot an unmixed boon. On the contrary, it involves ertain disadvantages and dangers; and the claim ere to be submitted is that it is the duty of the harmacopœia to provide safeguards against the isks which its official scheme of doses calls into xistence.

The Mischiefs of Pharmacopœial Doses.

The chief count in the indictment which may be rged against the existence of pharmacopœial doses is that they tend to hinder liberty of prescribing. Appearing in a volume enjoying a definite legal status, they acquire, almost inevitably, a certain official halo and sanction. So dignified, they are carried from the Pharmacopœia into the text-books of materia medica and therapeutics; and they form the general standards of examiners. Hence the medical student becomes accustomed to regard such doses as authoritative; and even the prescriber, influenced by his early habits, remains in greater or less measure sensible of their restraining influence and feels more or less acutely the advisability of keeping his prescriptions within the limits of the official figures. But efficient and successful prescribing is not cultivated by adherence to a system of rigid rules; it demands, rather, the djustment of doses of selected remedies to the eeds, peculiarities, and idiosyncrasies of the individual patient. Dangers no doubt attend excess, ut equally they attend defect. Against the one here are constant warnings, but the mischiefs of the imid and officially restricted prescriber are rarely ecited. These mischiefs, it is here contended, the xistence of a scheme of official doses tends to xcite and maintain. *It is therefore a fair claim* hat the promoters of such a scheme should take teps to avoid the harm of which it is capable. In hort, the doses of the Pharmacopœia ought to be resented in *such a fashion as to indicate clearly* that, while useful as an opportunity for discussion between dispenser and prescriber, they have no jurisdiction over the judgment and freedom of the physician.

That this is the true aim and purpose of the pharmacopœial doses there can be no question. In the preface to the official volume it is plainly stated that these doses "are not authoritatively enjoined," and that "the medical practitioner must act on his own responsibility as to the doses of any therapeutic agents which he may administer." But, buried in a preface, these statements are rarely revived as active and urgent doctrines. They seldom, if ever, penetrate into the manuals of materia medica and therapeutics, and probably many students pass through the curriculum without hearing of their existence. It is therefore no exaggeration to say that the intention of the Pharmacopœia in this respect is not achieved. The concealed wisdom of the preface rests undiscovered, while the impressive examples apparently afforded by the text carry a full influence. Accept this contention, and it follows, that if the true meaning of the pharmacopœial doses is to be widely appreciated, and if their unwholesome restraining influence on practice is to be avoided, something *more than the general propositions of the preface* is necessary. The limitations and qualifications there announced must be carried into the text of the volume, and this in such a fashion that in each individual instance there shall be a clear intimation that the "dose," as stated, is "not authoritatively enjoined," and that the official figures neither limit the judgment of the practitioner nor diminish his responsibility.

"*Pharmaceutical Dose.*"

The harm of the present position arises from the use, without qualification, of the word "dose." It is because they are presented in a fashion so *absolute, that the official figures* have *acquired* an authoritative quality to which they have no real title. The suggestion I now offer is that these figures should be deprived of their artificial prestige by the introduction of the limiting term "pharmaceutical"—that, in short, the "doses" of the Pharmacopœia should be printed and quoted as "pharmaceutical doses." Such a phrase would furnish an occasion to the teacher to explain to his pupils its meaning and necessity, and would be a permanent proclamation that neither the Pharmacopœia nor the General Medical Council cultivates the desire *either to give lessons in therapeutics* or to direct or control the judgment of the *prescriber*. Further, the term "pharmaceutical dose" can be defended as strictly accurate, for the doses announced in the Pharmacopœia are those which, appearing in a prescription, pharmacists may safely dispense without seeking the special and personal warrant of the physician—they are authoritative doses for members of the pharmaceutical craft or calling. "Pharmaceutical dose" is therefore both correct and appropriate; it indicates the real significance of the official figures, and also prevents them from being regarded as therapeutic lessons. Hence its adoption, without qualifying in any degree such advantages as the existence of a scheme of pharmacopœial doses ensures, would announce openly the freedom of the physician to act on his own judgment.

To take a single example. The dose of tincture of digitalis according to the [illegible] is 5 to 15 minims, and this, in the [illegible] preface, represents "the average range, in ordinary cases." With such a description there is no need to quarrel, but it would be absurd to suggest that the figures as quoted limit the amount of tincture of digitalis which the physician may prescribe. What is wanted is the plain and unambiguous proclamation in the pages of the Pharmacopœia that the pharmacopœial doses have no such limiting effect; and the adoption of the phrase "pharmaceutical dose" would, I suggest, secure this end.

If the necessity for a qualifying term is once allowed, there seems to be none so satisfactory as the one here proposed. "Official dose" would rather aggravate than help the present position, as it suggests authority and command; and "pharmacopœial dose" would have much the same note. Even "average dose" might propose the doubt whether what is formally defined as "average" could be safely exceeded—at least, in any considerable degree. "Pharmaceutical dose" both gets rid of all suggested pressure of official orthodoxy and authority and announces in accurate terms the modest function which it is the purpose of doses named in the national Pharmacopœia to satisfy. It preserves the public advantage, and lessens, or even avoids, the dangers carried by the existing practice.

The Metric System.

A second suggestion which I venture to advance is that the doses stated in the Pharmacopœia be stated in terms of the metric system. The advantages of this system are generally allowed, if not in commercial operations, at least in scientific weighings and measurings, where prescribing and dispensing may fairly be placed. Yet in these activities the metric notation makes little or no advance. Everyone applauds the method, but no one adopts the practice. In spite of the benedictions of congresses and editors, custom and habit maintain their supremacy and the revolution "evaporates in complimentary harangues."

The reason for this stagnation is not far to seek. It is found in the last resort in the practice of presenting the doses in the Pharmacopœia in terms of the imperial notation, and in this notation only. Almost inevitably, therefore, the doses of medicines appear in this guise in lectures and text-books, and are so acquired by students of medicine. Thus, the student necessarily learns to think and speak of doses in terms of the ordinary weights and measures. What he learns as a student he continues as a prescriber, and the dispenser, willingly or unwillingly, follows suit. The sequence is complete. The Pharmacopœia determines the speech of the teacher, text-book, and examiner; these in turn control the student; the prescriber is but the student writ large; and the prescription fixes the habit of the pharmacist. All find the ultimate reason, or excuse, for their adhesion to the imperial notation in the example and custom of the Pharmacopœia.

If, however, the pharmacopœial doses were written in metric terms the entire position would be changed. In lectures and text-books doses expressed in these terms would certainly appear. The student would therefore learn to think of doses in decimal quantities, and teachers and examiners, though doubtless with difficulty and reluctance, would be driven to the same habit. Accustomed in the days of his youth to think in metric terms, the prescriber, when his opportunity comes, will certainly write his pre-[illegible]ions in this language; and the dispenser [illegible] follow, without choice. In short, the key of the position for those who wish to see the adoption of the metric system in prescribing and dispensing, is the scheme of doses printed in the Pharmacopœia. Until this is captured the demands of preliminary examinations, and the invention of ingenious devices for the ready translation of ordinary weights and measures into metric equivalents, will be exercised in vain. In spite of these methods of pressure and persuasion the prescriber will continue to write in the terms in which he has been trained to think, and he will be trained to think in the imperial notation so long as this is the language of the doses of the Pharmacopœia. It is only by a change in this language that the adoption of the metric system in medicine and pharmacy can be attained; and it is to this essential point that the advocates of the metric system should address themselves.

Use of Metric System in Previous Editions.

Some amount of encouragement in the desired direction can be found in the history of the Pharmacopœia. In the preface to the issue of 1867 the General Medical Council recognised "the advantages that would result from the adoption of one uniform system of weights and measures," but felt unable to employ, "even as an alternative," a system which "as yet is to a great extent unknown in this country"; they did, however, sanction the metric terms to this extent, that authorised test solutions to be used for volumetric estimations were printed both in British weights and measures and in terms of the metric notation. In the 1885 edition no reference was made to the question of weights and measures, but as the preface to the 1867 edition was reprinted in the 1885 issue, the Council presumably agreed generally with the position there defined. In 1898 the alternative employment of metric weights and measures was extended to the main text of the Pharmacopœia, so that since this date it has been permissible to conduct all operations of weighing and measuring required in the manufacture of the official preparations, either in metric weights and measures, or in the weights and measures of the imperial notation. At the same time the alternative in reference to processes of gravimetric and volumetric analysis was abolished, and here the metric system alone appeared. The movement, in short, has been to offer alternative systems, first in the strictly analytical sections of the Pharmacopœia, and next in the manufacturing and pharmaceutical sections, and from this to advance, as in the case of the analytical section, to the metric system standing alone. The doses, however, have remained in terms of the imperial notation only. It would seem to be in harmony with the previous record that these should now be offered in metric terms; and this is the suggestion I here venture to propose.

Doses both in Metric Terms and Imperial Notation.

It is, however, only reasonable to allow that, at first, the metric terms may have to be offered merely as an alternative to the doses as at present stated. This would both follow precedent and would avoid the risk of detaching the Pharmacopœia from the habits and customs of the constituency with which it is concerned. After all, it has to be remembered that the Pharmacopœia is an instrument of education in an indirect sense only. In order that it may serve the public interest it must keep in touch with the existing state of medical practice. An abrupt presentation of the pharmacopœial doses in metric terms only would certainly mean a separation between the language of the

Pharmacopœia and that of the general body of prescribers; and such a separation would be out of harmony with the main purpose of the Pharmacopœia. But to offer the doses in terms both of the metric system and of the imperial notation, especially if the former were given the first rank, would give the decimal plan an opportunity with the prescribers of the future, without creating any division between the Pharmacopœia and the practitioners of the present day. No doubt, even if such a change is made, movement will be slow. But almost certainly there will be some movement, whereas, under existing conditions, the metric system in practical medicine and pharmacy gains many compliments, but makes no progress. It is in vain that advocates of this system address themselves to prescribers whose habits of thought and expression are already fixed; these are beyond hope and must be left in their sins. With the future generation there is some chance. But the Pharmacopœia must lead the way, and, in the fashion here proposed, it can do this without any sacrifice of the object and purpose for which, under the authority of the Legislature, it has been called into existence.

Harley street, W.

THE BISMUTH URETERAL CATHETER, COLLARGOL SOLUTION, AND BARIUM SULPHATE SUSPENSION IN THE DIAGNOSIS OF SOME URINARY DISEASES.

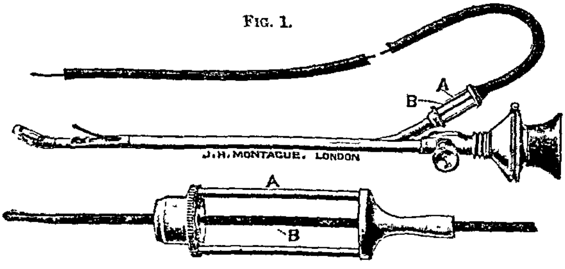
BY R. J. WILLAN, M.S. DURH., F.R.C.S. ENG.,
HONORARY SURGICAL REGISTRAR, ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE; DEMONSTRATOR IN SURGICAL PATHOLOGY, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

(*With Illustrative Plate.*)

Catheterisation of the Ureters.

As it is not possible to arrange to have the help of the same assistant every time I catheterise a ureter, I rely entirely upon myself for the performance of this operation. During an experience of six and a half years not a single patient has been infected, and this I attribute (1) to using strong antiseptics for my hands and (2) to the constant use of my aseptic ureteral catheter sheath which I introduced in 1907.

FIG. 1.



Author's aseptic ureteral catheterisation sheath

Aseptic ureteral catheterisation sheath.—This sheath (Fig. 1) reduces to a minimum the danger of carrying sepsis to the high urinary tract, and it comprises two detachable portions—namely, metal and rubber. The metal one consists of a perforated screw-cap and a conical-shaped portion (with broad base and funnelled apex); these another by two thin side rods m diagram. The screw-cap is a replica o the upper end of the compartment for tra the ureteral catheter of the Nitze catheter cystoscope. A piece of rubber tubing, 22 inc long and with a bore of one-eighth of an inch, completes the apparatus. The rubber tubing is made to slip over the bulbous bell-mouthed apex of the "cone," and the whole is screwed on to the cystoscope. The ureteral catheter having been introduced into the rubber tubing the catheter is pushed onwards. Owing to the funnel-shaped apex of the metal portion the catheter B readily enters the lumen of the "cone," reappears between the two metal connecting rods, and negotiates the orifice leading into the ureteral compartment of the cystoscope. When the *vis a tergo* has introduced the catheter as far as possible, grasp it between the thumb and index finger of the right hand and push onwards as required. The advantages of this sheath are obvious. It is simplicity itself. The present real dangers from sepsis owing to the catheter touching the operator's face, hair, and being breathed upon are avoided. It is easily sterilised, for both rubber and metal portions will boil. Excepting for the end remote from the tip there is no need to handle the ureteric catheter until it is well inside the cystoscope. The rubber tubing can lie anywhere, over the cystoscopist's shoulder, in between the patient's legs, &c. Without this addition there is a great liability for the catheter to double up at the point of handling when it is being pushed onwards; the opposing thumb and index finger slide up and down the side rods and give the necessary support. It is necessary to use a lubricant for the rubber tubing in order to make the catheter travel more easily; a suitable one is glycerine, and it may be introduced by a sterilised pipette. This sheath can be fitted to any cystoscope.

I usually wear rubber gloves during the operation. Just before the introduction of the cystoscope a sterilised cotton glove is put on to the right hand over the rubber glove, as this cannot grasp the slippery lubricated ureteral catheter.

Technique.—I always have the patient in the full supine position on a reasonably firm bed or couch. During the early part of my career I failed in one or two cases to get a catheter into the ureter entirely because the patient was lost in the depths of a feather bed! If possible a general anæsthetic is never employed. Anæsthesia undoubtedly interferes with the renal function, which interference renders it difficult to get an accurate record of the amount of work each kidney is capable of performing. Moreover, I have a wholesome dread of injecting, either by a syringe or by gravity, any fluid into the renal pelvis of a patient who is unconscious through anæsthesia.

To avoid inserting a catheter into the wrong ureter.—Experience has taught me that to insert a catheter into the wrong ureter is a matter of great ease, especially if the patient is restive during the catheterisation. I have made this mistake more than once, and Fig. 2 shows an X ray photograph, with abnormal shadows in the pelvis, where a bismuth bougie *is in the wrong ureter.* To avoid a recurrence of this mistake I now always put a blue pencil cross on the skin over Poupart's ligament of the side I wish to catheterise. This "cross" is constantly catching the operator's eye during the catheterisation and eliminates the source of error mentioned.

Mapping Out the Line of the Ureter.

To be able to map out the line of the ureter is of great use in the interpretation of any abnormal shadow in the situation of the renal pelvis, or line of the ureter. These abnormal shadows include a calculus *in* the pelvis of the kidney or the lumen of the ureter, also phleboliths, calcareous glands, and seminal vesical concretions (in the case of the male).

Methods of demonstrating the ureter.—These are (1) a silver stylet in the lumen of an ordinary ureter catheter; (2) a catheter, or bougie, impregnated with bismuth; and (3) collargol solution. Neither (1) nor (2) have proved to be quite satisfactory. Excepting in thin patients my results with the wire have not been very successful. The bismuth bougie and the catheter are both most unsatisfactory, for they are expensive, unreliable, and the deterioration is rapid; even if one capable of giving a good shadow is obtained, these bougies have a short, even if a useful, life. The last-mentioned method is, I think, the most certain way. The lumen of an ordinary ureter catheter is filled with a column of collargol solution, or the radiogram is taken while the collargol is trickling down the ureter from the renal pelvis. I understand that this method has now entirely replaced the use of the silver wire in the Mayo clinic.

Calculus in the renal pelvis.—Fig. 3 shows a bismuth bougie lying in the right ureter, and actually touching a large calculus in the pelvis of the right kidney. The patient was a young woman who seven years previously had had the appendix removed for persistent right iliac fossa pain; the operation of appendicectomy gave no relief. The calculus was subsequently removed by Professor Rutherford Morison, and the patient did well.

Calculus in the ureter.—Fig. 4 shows a bismuth bougie touching a stone. In such a case as this, with a stone lying in the lower end of the ureter, it is important not to move the cystoscope until the radiogram has been secured, otherwise there is a great danger of the catheter being withdrawn to a slight degree, and it will then fail to touch the stone. In this case the stone had been lodged in the same situation for some weeks previously. Dilatation of the ureteric orifice was sufficient to enable the stone, which was a spiculated one, to pass, and the patient voided it per urethram.

Shadows outside the ureter.—Fig. 5 demonstrates shadows in the pelvis, which by means of the bismuth bougie were proved to be away from the line of the ureter. The patient had previously passed renal calculi, which he showed to his medical attendant, and after a radiogram had been secured showing shadows in the pelvis he was sent to have these removed by operation. Fortunately for the patient, the bismuth bougie showed that the abnormal shadows were not calculi, and he was spared a useless operation.

To illustrate the necessity of sometimes mapping out not only the line of the ureter but also the renal pelvis.—Fig. 6 illustrates the necessity of not only using a bismuth bougie, but of employing collargol. This patient complained of right-sided renal colic, and X rays on two separate occasions showed a shadow in the same situation. A bismuth bougie was inserted as far as the renal pelvis, showing that the shadows were external to the line of the ureter. These shadows were then interpreted to be in the lower pole of the kidney. Had pyelography been resorted to in this case I feel quite sure that I would have been able to have shown that these shadows were away from the kidney altogether; that they were not renal calculi was subsequently proved by operation.

Pyelography.

Voelcher, of Heidelberg, ingeniously conceived the idea of mapping out the renal pelvis with collargol solution in order to gain information as to its size, shape, and position. This was enthusiastically taken up by Braasch, who recently recorded having successfully done over 1000 cases by this method.

Strength of collargol solution used.—With regard to the degree of dilution of the collargol, I have used solutions varying from 3 to 20 per cent., but 10 per cent. is the strength usually employed. The strength of the solution largely depends (1) upon the stoutness of the patient; (2) upon the degree of a hydronephrosis (if such be present), which it is impossible, as a rule, to empty completely through the ureter catheter, and which results in a further dilution of the collargol solution; and (3) if an abnormal shadow has been seen in the situation of the renal pelvis a weak solution must be employed, for should a stone be lying in the pelvis or a calyx and too strong a solution used, the probability is that the calculus shadow will be obliterated by the collargol shadow.

Effects of collargol.—Various dangers in the injection of collargol have been mentioned. In addition to sepsis Oehlbecker reports a case where there were areas of necrosis, infarction, and cast formation after the renal pelvis had been distended under high pressure. Zacharisson found casts one year after injecting the healthy kidney; Jewell reports embolic gangrene; while Eckehorn records a case of œdema of the kidney. In order to ascertain the truth of these statements Strassmann experimented on live rabbits, and came to the conclusion that the injection of collargol in proper amounts and under moderate and careful pressure into the renal pelvis does not produce harmful results and in no way brings about noteworthy changes in the pelvis of the kidney.

I have now injected collargol in a large number of cases without any ill after-effect. Braasch also reports over 1000 cases without any harmful result. I have had one case where a considerable quantity of collargol lay in a hydronephrotic kidney for a fortnight without doing any harm whatever, the condition being found at operation. If I

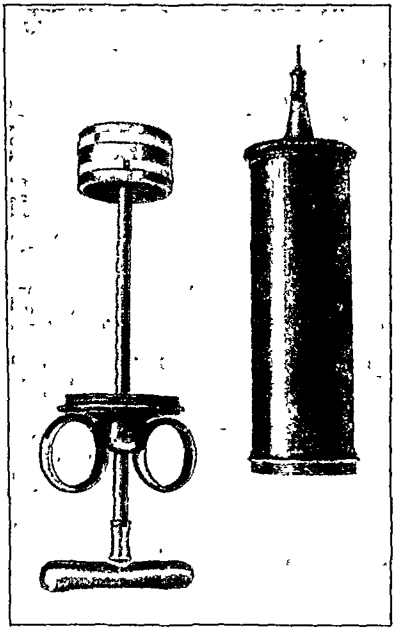
FIG. 12.—Showing bladder distended with barium sulphate solution in oil.

Make a collargol injection for diagnostic purposes the renal pelvis is emptied through the ureter catheter before the latter is withdrawn. If, however, the collargol is injected for purposes of medication, then it is not withdrawn, but left to find its own way out. I feel satisfied, therefore, that where harm has been done it has been due to over-distension of the renal pelvis, amounting, perhaps, to even rupture, and in all these cases the patient was probably under a general anæsthetic.

FIG 13.



Syringe and piston

Technique of injection without a general anæsthetic.—After getting the ureter catheter *in situ* the kidney area is palpated to empty a hydronephrosis, if such be present, and in any case I collect sufficient urine to make a complete examination before proceeding to inject the collargol. In this way the catheterisation serves two separate useful purposes: (1) the renal function is estimated; and (2) the degree of any hydronephrosis is ascertained. The collargol is then injected with a syringe if the patient has not had an anæsthetic, or by means of gravity if an anæsthetic has been employed.

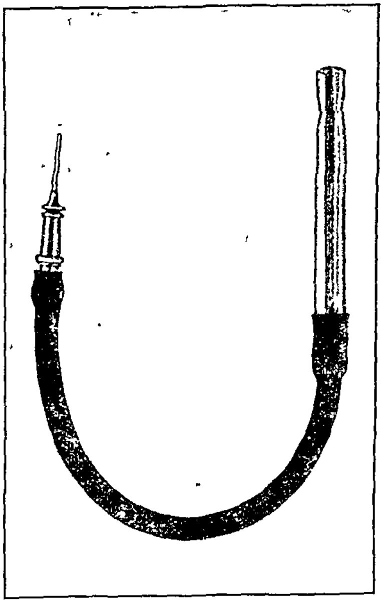
To obtain a syringe which is satisfactory for the purpose of injection has been a matter of no small difficulty, owing to leakage past the piston. It is necessary to have a syringe of about four ounces capacity and one easily sterilised. The piston must work easily; although if it is too free then the solution leaks past the piston and the actual amount injected into the renal pelvis is unknown. The piston of the syringe I now use has two rings on it, and these prevent any leakage past of the collargol solution. (Fig. 13.) The lumen of the barrel should be lubricated with sterile vaseline before sterilisation of the syringe in order to facilitate its working. The metal rod connecting the piston to the handle is marked off in 5 centimetres in order that the amount of solution injected can be easily ascertained.

It is absolutely essential to make the injection slowly. As the lumen of the ureteric catheter is very small the nozzle of the syringe must also be of small calibre. The funnel of a ureter catheter is of little use to me, as I usually withdraw the cystoscope and leave the catheter *in situ*, and of course the large funnel cannot travel along the small compartment of the cystoscope.

If it is desired accurately to determine the degree of hydronephrosis the ureteric orifice must be watched by means of the cystoscope during the injection of the collargol. Immediately the black-coloured fluid runs into the bladder alongside the catheter the operator knows that the limit of distension of that renal pelvis has been reached.

Technique of injection with a general anæsthetic.—For injecting collargol where the patient is under an anæsthetic I ascertain if possible the size of the renal pelvis by bimanually compressing the same, and carefully measure any urine secured. It is only safe to allow a similar amount of collargol to run into the renal pelvis, and even then I use an irrigator attached to the small nozzle by flexible rubber tubing, this nozzle being of smaller size than that of the syringe. (Fig. 14) The collargol solution is allowed to run in by gravity.

FIG 14.



Irrigator and nozzle.

I attach great importance to the distension of the renal pelvis *without* a general anæsthetic, for the patient can promptly indicate when sufficient has

0·5 or in 1 per cent. iron-alum instead of a 2½ per cent. solution, as the feebler solutions decolorise more uniformly and thereby prevent a too rapid decolorisation of the nuclei containing only slight amounts of nucleo-protein. While decolorising the slides should be constantly moved. In studying gland cells Ehrlich's triacid stain gave good results; for determining basicity 0·5 per cent. toluidin blue is good, and if no differentiation with alcohol is contemplated I use a 1:1000 toluidin blue and examine with a Zeiss D* lens. For general all-round staining I have found my long methyl-blue-eosin method to give the best results, as this method allows us not only to study cytoplasmic changes in individual cells, but also permits of a thorough investigation of alterations in nerve fibres, in the matrix of hyaline cartilage and of the cornea, and in the white matter of the cord and the brain and the peripheral nerves.

In my investigation special attention was paid to the epithelium of the conjunctiva, the cornea proper, the retina, the cartilaginous capsule of the eye; the brachial nerve with its spinal and sympathetic ganglia[2]; the cerebrum, thalamus, midbrain, medulla, and upper part of the cord; the alimentary canal from the œsophagus to the anus; and the thyroid gland, the liver, and the pancreas. The kidneys and the suprarenals were not studied by me, as these organs are being specially investigated in my laboratory by Dr. H. W. E. Walther from the secretory point of view.

Generally speaking, the somatic cells of all higher animals may be divided into two classes, the first of which includes all gland cells and nerve cells, while the second class is represented by the protective coverings and the organs of locomotion—namely, muscles, tendons, and bones. The blood occupies a position somewhat intermediate. My reason for this classification is as follows. In the introductory remarks it was pointed out that in each cell there is an "indispensable" moiety of protein. This latter includes all secretions formed by gland cells and by nerve cells; thus, if the stomach or pancreas cells once have formed zymogen granules, then these granules cannot be made use of for the general maintenance of the animal, and nothing but a specific stimulus will set the secretions free. However much the cytoplasm between the zymogen granules is reduced, the zymogen itself undergoes no apparent diminution in starvation. Similarly, in nerve cells, when the Nissl substance has been once formed, and it is quite immaterial whether the latter remains in the nucleus, as in the nuclei of the rods in the retina, or is excreted into the body of the cell, as in all other mammalian nerve cells—nothing will call forth a diminution of the Nissl substance except functional activity, for I have found months of starvation in the frog and three weeks' starvation in the rabbit to leave the Nissl substance undiminished if care be taken to let neither light, sound, odours, temperature, or touch influence the animal experimented on. From the teleological point of view, which is the same as that of common sense, if glandular secretions, or if Nissl's substance, were used up for purposes of general economy, then on food being administered to a starving animal the food could not be digested, nor would the nerve cells be able to bring about movements of muscle fibres or of gland cells.

On the one hand, we find therefore a conservation of potential energy in the starving cells; on the other hand, a constant loss of energy by the liberation of albuminous compounds owing to a continual secretion of the one or more digesting enzymes.

This explanation will account for the rapid diminution in the amount of "available" protein which takes place as soon as food is withheld. We know of both ereptic and tryptic enzymes being widely distributed over the body, and it must be these or analogous enzymes which bring about the liberation of amino-acids, making it thereby possible for one organ to nourish other organs—for example, ordinary skeletal muscle to nourish the heart &c.[3] The loss of protein brought about by auto-digestion must be made good, and therefore it is necessary to save the "available" protein as much as possible by the administration of readily digestible albuminous food, such as caseinogen, in sufficiently large quantities to avoid an undue diminution of the "available" protein. The average amount of protein should be 1 gramme for every kilogramme of body weight per day, and in cases of nervous debility this amount should be doubled. The fact that after the administration of milk proteins there is produced within at the most two hours a demonstrable increase in the density of the cytoplasm of the most diverse cells shows, however, that in addition to the disruptive or digesting cell enzymes there must be at work constructive or "coagulating" enzymes; and it shows, further, that the maintenance of the cell is dependent on the balance between the disruptive and the constructive enzymes.

After the administration of the sanatogen, in addition to the changes in the cell bodies just alluded to, the next most striking change is the increase in the affinity for basic dyes shown by the cell nuclei. This increase is partly due to an actual increase in the size and the number of the chromatic elements, consisting of nucleo-protein, and partly due to the nuclear sap or nucleoplasm—forming the greater bulk of the nucleus—developing a greater affinity for basic dyes, which means becoming more acid itself.

The two facts just mentioned are brought out by the illustrations (Figs. 1 to 7), which are partly exact representations of cell nuclei, magnified 1000 linear diameters, partly diagrams showing exactly the amount of change in the intensity of staining produced by feeding with sanatogen. Fig. 1 represents nuclei of the cornea seen from before backwards as each eye was cut in the coronal plane; *a* and *b* are taken from the two unfed controls, *c* represents the increase in the nucleo-protein three hours after feeding, *d* five hours after feeding and *e* 89 hours after feeding. Fig. 2, *a*, shows two unfed nuclei from the cartilaginous sclerotic coat, and *b* two fed nuclei three hours after feeding.

Fig. 3 shows the changes in the heart muscle; *a* and *b* represent the isotropous and *c* and *d* the anisotropous substance; *a* and *b* after staining with my long methyl-blue-eosin method, and *c* and *d* after staining with iron-alum-hæmatoxylin; *a* and *c* are the unfed hearts, and *b* and *d* hearts two hours after feeding. Fig. 4, *a* to *f*, shows the nuclei of the heart muscle in different stages of contraction and also in the uncontracted state. It is exceedingly difficult to find corresponding trabeculæ in two different hearts, but as to the change in the nuclei there cannot be any doubt; *a*, *b*, and *c* are from the unfed, and *d*, *e*, and *f* from a frog fed two hours previously. Fig. 5 shows the change produced in the conducting parts of the nervous system, especially in the non-cellular part; *a* is the unfed and *b* the fed condition five hours after feeding. Fig. 6 shows the nuclei of ependyma cells with their long tail-like processes pointing toward the central canal of the spinal cord or towards the ventricles; *a*, *b*, and *c* are unfed; *d* is three hours after feeding, *e* and *f* 12 hours, *g* 24 hours, and *h* 68 hours after feeding. Fig. 7 shows small nerve cells from the midbrain, *a* from the unfed, and *b* from a frog five hours after feeding.

---

[2] I found constantly a definite sympathetic ganglion on the brachial nerves of the North American frogs.

[3] Experiments are under way in my laboratory to determine whether ferments are more abundant during starvation.

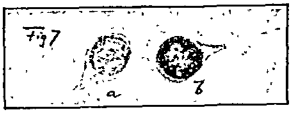
Nuclei of ependyma cells.



Small nerve cells from the midbrain.

The above illustrations show that after feeding on milk protein—

1. Cells living away from the actual blood stream—for example, the corneal cells (Fig. 1) and cartilage cells (Fig. 2)—will benefit within a very short time after the administration of food, as judged by the increased activity of their nuclei.

2. During prolonged starvation the heart muscle undergoes marked atrophy, which shows itself in both the isotropic and the anisotropic parts of the muscle fibrils losing approximately 25 per cent. of their stain ability when compared to normal non-starved animals (see Fig. 3). It was further seen that two to three hours after feeding on milk protein the muscle fibrils show a marked recuperation, as evidenced by the sarcostyles staining much more deeply, both after iron-alum-hæmatoxylin staining, which stains the anisotropous substance, and after my long methyl-blue-eosin method, which stains both the isotropous and anisotropous substances. In all the fed frogs, within one hour after feeding the nuclei of the heart muscle (Fig. 4) showed a distinct change, the nucleo-protein content was increased, and the nucleoplasm stained much more deeply.

Whether the nuclear activity is antecedent to the increase in the isotropous and anisotropous substances or not I have not been able to determine definitely, and this also holds good for all the other cells in the body, but my general impression is that nuclear activity precedes cell activity.

3. Comparing sections of the nervous system of

starved and of fed animals, stained in exactly the same way, by holding the microscopic slides (especially those stained by my long methyl-blue-eosin method and well differentiated) at arm's length, the sections of the brain, medulla, and spinal cord of the starved animals appeared much paler than did the sections of the fed animals. (Fig. 5.) This difference is much less evident when the sections are stained deeply or when they are compared with one another under the low power of the microscope. In sections stained with toluidin blue, iron-alum-hæmatoxylin, or Ehrlich's acid hæmatein, with a Zeiss C lens, the nuclei of the ependyma cells (Fig. 6), lining the ventricles and the central canal of the spinal cord, were always much more deeply stained in the fed frogs than in the starved ones. The same holds good for the small nerve cells (Fig. 7) in the deeper layers of the anterior and the posterior corpora quadrigemina.[4] Changes in the larger nerve cells were not so unequivocal as to allow me to draw any definite conclusion, and this also holds good for the spinal and the sympathetic ganglia, because functional activity tends to diminish the Nissl granules, while feeding increases nuclear activity and the tendency towards the formation of Nissl's substance.

Marked changes, similar to those in the heart (see Fig. 4), were seen, however, in the brachial nerves, especially in the nuclei of the sheath cells forming the medullary covering to the axis cylinders. Within one hour after feeding the nuclei commenced to swell and to stain more intensely, making it probable that the nuclei of the sheath cells have to do with the nourishment of the axis cylinders, especially as the connective-tissue nuclei of the epi- and the peri-neurium also showed an increased affinity for basic dyes in the fed specimens, but to a much less extent than did the nuclei of the sheath cells.

After iron-alum-hæmatoxylin, and also after my long methyl-blue-eosin method, the brachial nerves of starved animals stained more feebly than did those of fed ones (see Fig. 5); the difference was not very marked, but notwithstanding this quite distinct. The increased depth of staining of the nerves in the fed frogs showed that a building-up process goes on in the nerves after the administration of albuminous foods.

As the questions involved are so important I submitted my slides on the heart and on the nervous system to my colleague, Professor Irving Hardesty, who after a careful examination agreed with my findings. I wish to use this opportunity to thank Professor Hardesty for the courtesy shown me.

General conclusions.—Starvation leads invariably to a rarefaction of the cell body and its processes, as is evidenced by the diminished staining power of the cell plasm of all cells in the body. Thus in all starved animals the contractile elements of the heart, both the isotropous and the anisotropous, undergo an atrophy amounting to 25 per cent. of the normal state.

The nervous system also suffers during starvation to a much greater extent than ordinary measurements by weight would lead one to suppose. This loss, if stimulation of the nervous system is eliminated, is restricted to the conducting paths, as is proved by both the nerve cells (apart from Nissl's substance) and also the nerve fibres staining much less deeply in starved than in fed animals. That Nissl's substance is diminished during functional activity I have proved previously.

Feeding with sodium caseinogenate containing 5 per cent. of sodium glycerophosphate it is possible within two hours to get a definite increase in the nuclear activity even of cells which are not supplied directly by the blood, as, for example, in the cornea and in cartilage. This milk protein further leads to an increased depth of staining of the heart muscle and of nerve fibres, and this deeper staining it is impossible to explain in any other way, except to assume that the amino-acids liberated by the digestion of the caseinogen are actually built up into what I have termed the "available" protein.

From the conservation of protein point of view, as well as from that of restoration, it is absolutely necessary to have a non-purin-containing, easily digestible albumin. From the evolutionary point of view milk protein must be the best, as it took millions of years of elimination to make it into what it is now; and yet, time after time, I have found white of egg given to invalids as if it could make good the loss brought about by starvation. That white of egg by itself is an insufficient food for the nervous system seems to be proved by a fact to which Dr. E. A. Eustis casually drew my attention —namely, that the beri-beri neuritis of birds is not cured by the white of egg, while it is cured if the yelk be given. Caseinogen with its phosphorus content and other radicals is to the mammal what the yelk and the white of egg together are to the fowl. Neither of these foods contains purin, but, being mammals, let us give in fevers and in all cases of debility milk protein in preference to eggs, especially as *erepsin* by itself is capable of digesting caseinogen. Let us further give a minimal amount of the fats of milk, just sufficient to bring the calories up to 3500 or 4000, especially when we are dealing with adults, and thereby hasten absorption of the amino-acids and also the liberation of waste nitrogen by the liver. Milk sugar, because of its slow conversion into its monosaccharides, and therefore steady supply of potential heat, should be left for calorific purposes in combination with caseinogen, and we should endeavour to get the full calorific value of the food, beyond the 800 calories got from the caseinogen in cases of fever and debility, by administering milk sugar in the first instance and other carbohydrates secondarily.

New Orleans.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: LECTURE ARRANGEMENTS.—The following are the subjects of the Hunterian Lectures for 1914. Mr. Hastings Gilford will deliver two lectures, on Feb. 2nd and 4th, on Infantilism; Mr. E. W. Hey Groves, one lecture, on Feb. 6th, on Experimental Production and Treatment of Fractures in Lower Animals; Professor A. Rendle Short, one lecture, on Feb. 9th, on Changes in the Blood in the Causation of Surgical Shock; Mr. H. Beckwith Whitehouse, one lecture, on Feb. 13th, on the Pathology and Causation of Idiopathic Uterine Hæmorrhage; Professor Arthur Keith, six lectures, on Feb. 16th, 18th, 20th, 23rd, 25th, and 27th, on the Evolution, Anatomy, and Diseases of the Anthropoid Apes; Mr. C. Mansell Moullin, one lecture, on March 9th, entitled Further Observations upon the Biology and Classification of Tumours. The Arris and Gale lectures will be delivered as follows: one lecture, on March 2nd, by Dr. David Waterston, on Some Recent Researches in Human Development; and two lectures, on March 4th and 6th, by Dr. F. Wood Jones, on the Morphology of the External Genitals. All the above lectures will be delivered at 5 o'clock P.M. precisely at the College, Lincoln's Inn-fields, W.C.

THE TOLERATION OF ARSENIC BY THE HUMAN SYSTEM.

BY H. G. A. HARDING, A.I.C., F C.S., &c.,
TEACHER OF CHEMISTRY, UNIVERSITY OF SYDNEY AND SYDNEY TECHNICAL COLLEGE; ANALYST UNDER PURE FOOD ACT, 1908, ETC.

THE toleration by the human system of arsenic has been so much discussed during recent years, and such various amounts have been stated, in many cases apparently without the slightest authenticity, that I decided during 1912 to conduct some experiments myself, the results of which could be placed on record with the confidence of being authentic. The experiments are summarised in the following.

It has been very generally accepted that the safe limits in dosage of arsenious oxide, As_2O_3 (white arsenic), lie between 1/60 gr. and 1/15 gr. (*vide* various pharmacopœias). A start was therefore made by taking 1/60 gr. doses thrice daily immediately after food, it being well known among medical men that even small doses of arsenic taken on an empty stomach may upset the system. After taking this quantity in this manner for four days, during which no effect, either beneficial or injurious, was felt, estimations were made of the quantity of the drug passed in the urine. The daily dose totalled 1/20 gr., and analysis of an aliquot part of the urine passed in 24 hours yielded 1/60 gr. per diem, thus showing 3/100 gr. per diem otherwise disposed of.

At this stage the urine was otherwise normal. The dose was now gradually increased to 1/30 gr. thrice daily and then to 1/20 gr. and 1/15 gr. The drug now showed in every lot of urine passed, and careful estimations of the amounts present denoted that a fairly even percentage was eliminated through this channel, the average being 25 per cent. to 30 per cent. of the amount of the drug consumed. The quantity of arsenic was always estimated by retaining the whole of the urine passed in 24 hours and taking of this an aliquot part. At this stage two further distinct experiments were made.

A. Doses of 1/15 gr. were taken on an empty stomach thrice daily. The result was that the system became irritated and a distinct feeling of discomfort was experienced lasting over two hours. Estimations of the amount of arsenic now showed a marked increase, 75 per cent. of the amount consumed appearing in the urine. This was discontinued after two days.

B. A comparatively large jump was made in the amount of arsenic taken, ⅛ gr. being taken as a single administration. This also produced irritability and uncomfortable abdominal pains of a more or less severe character. The effect lasted 4¼ hours and then passed off slowly. The whole of the urine passed during the subsequent 24 hours was collected, and on analysis yielded 1/12 gr. arsenic.

Recourse was now had again to the old dosage of 1/15 gr., and after the system became quite normal again the dose was increased to 1/12 gr., then to 1/10 gr., 1/9 gr., and to ⅛ gr. By thus going gradually to ⅛ gr. it was found that the amount was quite well tolerated without any discomfort or marked changes, and, moreover, the average percentage of the drug appearing in the urine was maintained. At this stage, but *not before*, the urine began to depart from normal. The amount of urea increased, the colour was always a little darker, the potash salts increased, and there were distinct traces of broken-down tissue present. The experiments were pushed further ahead, and the dose, still thrice daily after food, was increased to ¼ gr., ⅓ gr., and ½ gr. The urine became correspondingly more pronounced in the directions set out above, but there was no other change, save that it was found desirable or necessary to keep longer on each new increased dose before passing to the next highest.

Proceeding still onward the doses were increased to ⅔ gr., ¾ gr., ⅚ gr., *1 gr.* At this point it was felt in every way that the limit was being approached. Tissue became more apparent in the urine, though the percentage of arsenic remained at the average observed during the administration of the smaller doses. The potash salts and urea were still further increased. It was found, too, that the drug could only be taken with comfort if dry foodstuffs were consumed at meals—if liquid beverages were partaken of, or if the food was of the sloppy order, the administration of the grain dose of As_2O_3 produced immediate discomfort and burning pains in the abdomen, lasting 40 minutes to 1 hour and acting as a distinct aperient within 3 hours.

The next and highest dose reached was 1⅛ gr., which produced irritability and distinct and lasting discomfort every way it was taken and all precautions notwithstanding. Its aperient properties amounted consistently to almost purging, whilst the urine became more abnormal in the directions already indicated. Before taking this 1⅛ gr. dose I felt well in every way, and had increased 2¼ lb. in weight. I now discontinued the drug altogether, but immediately felt a fulness after meals and suffered general derangement for several days. The thought then struck me to keep on with the drug, but to decrease the amount daily. This I did accordingly, and in one week was able to reach ⅛ gr. only, and in less than another week dispensed with the arsenic altogether without any of the symptoms above mentioned, whilst the urine quickly regained normal again. Arsenic was, however, detected qualitatively in all samples of urine for 11 days after consuming the last dose of arsenic. My bodily weight again went to normal, as did the urine and all other functions. I felt well, and my health was quite normal again in every detail, except in one important particular, which must be recorded. It is this. Before the treatment I had not been in the least susceptible to nasal or any other form of catarrh, and, in fact, my opsonic index to that disease had been particularly high. After the treatment, however, a great change in this direction took place, for my opsonic index was continually low, and I was afflicted with nasal catarrh, or "cold in the head," surprisingly regularly every 21 or 22 days. The regularity of these attacks was so marked that I drew several of my medical friends' attention to it. The following mixture gave me most relief, and the attacks passed off suddenly within about 72 hours: Antipyrin, gr. iii.; sod. salicylas, gr. v.; chlorof., m. i.; tr. quininæ ammon. ad ℥ss. These attacks occurred in all 14 times at intervals of three weeks, and then after a rather worse one than usual ceased altogether, and for five months I have been quite free and normal, and my opsonic index has also gone up. There is no doubt in my mind that the attacks were brought on absolutely by the treatment.

The weighings of As_2O_3 for the doses taken were checked either by Mr. F. J. Shephard, M.P.S., pharmacist, or by Mr. W. J. C. Ross, B.Sc., F.G.S., lecturer in chemistry, to whom my thanks are due.

Sydney.

Clinical Notes:
MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A SIMPLE AND RAPID METHOD OF ADMINISTERING NEOSALVARSAN.

By Douglas J. Guthrie, M.D. Edin.,

LATE CLINICAL ASSISTANT AT THE ST. LOUIS HOSPITAL, PARIS.

Although neosalvarsan is so extensively employed in the treatment of syphilis, there appears to be no general agreement as to the best mode of administration. In this country it is usually dissolved in a large quantity (200 to 300 c.c.) of saline solution and injected intravenously. A much simpler method is that which was adopted at the St. Louis Hospital, Paris, over a year ago, and has since been in daily use there. It consists in the employment of a concentrated solution of the drug in distilled water. The technical details are as follows. The patient's arm is prepared in the usual manner. 10 c.c. of *cold boiled* distilled water are measured into a sterilised beaker, and the required dose of neosalvarsan, which may range from 30 to 90 centigrammes, is then added. The resultant solution is practically isotonic with the blood and may be safely used for intravenous injection. The only apparatus required is a glass syringe of 10 c.c. capacity. A short piece of glass tubing, containing a plug of sterile gauze, is fitted to the nozzle of the syringe in place of the needle before the solution is aspirated from the beaker. By this simple expedient the solution is filtered and the risk of injecting undissolved particles of the drug is obviated. The filter is now replaced by the needle and the injection proceeded with. As the needle punctures the vein dark blood will be observed flowing into the syringe. At this moment an assistant removes the constricting band from the arm and the piston is slowly pressed home. The whole procedure may be carried out in about two minutes, and my personal experience of it in practice has been in all cases most favourable.

The following advantages may be claimed for the method: 1. No saline solution is required, but simply a small quantity of distilled water which has been recently boiled and allowed to cool. 2. The apparatus is of a simple nature and may be easily and completely sterilised by boiling. 3. The rapidity of the method lessens the risk of any oxidation taking place.

Edinburgh.

A NEW TREATMENT FOR RINGWORM.

By C. Hughes Foley, M.B., B.Ch. R.U.I.

Ringworm is such an intractable disease, such a bugbear to schoolmasters and parents of children attending school, that any quicker and more efficient treatment than that known to us at present would be welcomed. Hence I am glad to bring before school medical officers and others a very simple and efficient treatment which leads to rapid cure.

The part being first washed with a strong solution of sodium bicarbonate, is next swabbed with a piece of lint moistened with spt. ætheris—to remove grease. It is next dried, painted with tinct. iodi, and an ethyl chloride spray immediately applied. I find it best to work with a pair of ethyl chloride tubes in each hand, as I thus cover a larger area in quicker time. The deeper the disease process the longer the spray must be applied. I spray until the integument gets china white, then I cease. It will be found that in from 24 to 48 hours the patch of ringworm has become quiescent. Next little tiny spots should be looked for and treated in a similar manner, when they also disappear in from a few days to a week. In ringworm of the scalp three or four applications of iodine and spray are required, but on the face or smooth surfaces one application suffices.

I have succeeded in curing ringworm of months' standing in one week by this method, and it has never failed me since I first thought it out last year. In most of my cases the patients were infected by handling cattle and calves. I should be glad to hear of the experience of others, whom I would urge to try it.

Ardrahan, co. Galway.

REDUCTION OF SHOULDER DISLOCATIONS.

By Julius Cæsar, F.R.C.S. Irel., &c.

That all dislocations of the shoulder are troublesome, and at times impossible of reduction without an anæsthetic if the routine as set forth in works on surgery be followed, will, I think, be admitted by all surgeons who have had any experience in these cases. Taking this view of the matter I submit for the consideration of the profession a practice I have carried out for the past 25 years with uniform success in those forms of the dislocations which have come under my care—viz. subglenoid, subcoracoid, and subscapular; of subclavicular I have had no experience. I have reduced these dislocations in the feeble youth of 15, the muscular carter and the ex-soldier with equal facility and without giving rise to the least pain or anxiety as to injury to vessels or nerves; and have carried out the practice on the sea-beach and the road as readily as in my surgery. The only adjunct required is the help of a third party to control the sound arm.

My mode of procedure is the acme of simplicity, and is as follows. Having divested my patient of all clothing necessary—it is not always requisite to remove the vest and shirt—I place him on the ground in a sitting position and grasp the wrist of the injured side, the third party doing the same with the sound one. We then raise both arms straight above the head, taking care to keep them parallel, and extending them upwards till the patient is just raised from the ground, at which point a click is heard and felt and the dislocation is reduced without further manipulation, except that occasionally in cases of subscapular dislocation it may be necessary to slightly rotate the arm from right to left in the case of left and from left to right in that of the right arm. These movements are, of course, carried out during extension.

Ilchester, Somerset.

Garden Cities and Town Planning Association.—The annual meeting of this association will take place at the Carpenters' Hall, Throgmorton-street, on Feb. 16th, at 4 p.m. It is proposed to deal with the economic aspect of the true garden city scheme, and a brief lantern lecture will be given illustrating the position of the garden city movement at the present time. Cards of invitation to the meeting can be obtained from the secretary, 3, Gray's Inn-place, Gray's Inn, W.C.

Medical Societies.

ROYAL SOCIETY OF MEDICINE

SURGICAL SECTION

Nephropexy and its Results

A MEETING of this section was held on Jan 13th Mr G H MAKINS the President, being in the chair

Mr G PERCIVAL MILLS opened a discussion on Nephropexy and its Results He said that his paper was based upon an attempt to investigate and impartially to consider the results of nephropexy by following up and examining a series of cases operated on by various surgeons in the General Hospital, Birmingham The results fell into two sections A, the mechanical results, and B the functional results A The mechanical results were shown in the following table —

	Fixed high (per cent)	Fixed low (per cent)	Relapsed (per cent)
(*a*) All cases	53	23	23
(*b*) Fixation to rib + capsular suspension sutures	73	0	26
(*c*) Suspension sutures only	62	12	25
(*d*) Suture to muscles of loin	12	75	12

He said that the superiority of operations *b* and *c* was obvious from these figures for though *d* showed fewer relapses than did any other method it usually resulted in a low fixation associated with a bad functional result Of cases in which a fairly efficient operation had been performed two years ago or less 23 per cent were found to be relapsed, of cases similarly *operated on three and four years ago 28 per cent* were relapsed The great majority of relapses therefore occurred during the first two years B The functional results were recorded entirely from the statements made by the patients themselves and had been tabulated in such a way as to indicate if possible the class of case in which operation was likely to be successful The gross results were thoroughly bad showing only 33 per cent of cures A class of case characterised by chronic lumbar pain only unassociated with any neuroses gave a rather better result—i e 50 per cent of cures On the other hand in those cases in which the lumbar pain was associated with general symptoms, such as headache, gastric discomfort depression or "nervousness," the percentage of cures fell to 9 The more the symptoms were confined to the affected loin the more probable was a cure by nephropexy A further analysis of the symptoms showed the possibility of grouping together a series of cases in which uncomplicated lumbar pain was *quite definitely relieved by rest in the horizontal position* In this group 75 per cent of the cases were cured this being the best result obtained from any group of cases On the other hand in the group of cases in which uncomplicated lumbar pain was *not relieved by rest* not a single case was cured by nephropexy The tabulated results were as follows —

Gross results (57 cases) ..	33 per cent cured
Cases with lumbar pain only (34 cases)	50 „ „
Cases of lumbar pain + dyspepsia or some neurosis (21 cases)	9 „ „
Cases of uncomplicated lumbar pain relieved by horizontal rest (20 cases)	75 „ „
Cases of uncomplicated lumbar pain unrelieved by horizontal rest (10 cases)	None cured

The following were his conclusions —1 The general

the persistence of the symptoms after a successful operation 3 The symptoms due to a movable kidney were chronic lumbar pain of the renal type described which was absolutely relieved only by horizontal rest These symptoms if present alone were nearly always cured by nephropexy 4 When lumbar pain was associated with neurotic symptoms, nephropexy rarely gave relief 5 Nephropexy failed to cure cases of dyspepsia which were supposed to be due to obstruction of the duodenum by a right movable kidney (of five such cases in the series none were cured) 6 The indications for nephropexy in a case of movable kidney were as follows (*a*) Intermittent hydronephrosis, (*b*) pain of the character described above, and (*c*) possibly in a few cases of Glénard's disease

Mr J W THOMSON WALKER said that there was probably no other operation where the results depended so closely upon the proper selection of cases as in that performed for movable kidney When we spoke of late results we were entitled to ask for some account of the class of cases operated upon and what manner of operation was performed He would discuss the question on these lines I What class of patients were operated upon? Leaving aside cases where a movable kidney was discovered and no symptoms were present (cases which everyone agreed should be left alone) there remained (*a*) those in which there were symptoms directly connected with the kidney, such as definite renal pain, hæmaturia casts albumin, and (*b*) those in which there were symptoms not directly referred to the kidney This class admitted of further subdivision into (1) Cases with gastro intestinal symptoms and (2) cases with nervous symptoms With regard to the first class of cases where there were symptoms definitely renal in origin operation should be performed, and the results, if the operation were successful in fixing the kidney, would be uniformly good He had not had a single case in this class which did not lose all symptoms after operation Turning now to the second class of cases In those patients who complained of gastro intestinal symptoms, these symptoms were due to dragging or to adhesion between the kidney and the duodenum and colon Sir Arbuthnot Lane had pointed out, and Mr Walker's experience was in entire agreement with what he said, that adhesions around the cæcum and colon might be a contributory cause in the production of movable kidney by dragging on that organ We should therefore be very careful in these cases with gastro intestinal symptoms that we did not operate on the kidney when the trouble was much more extensive affecting the bowel primarily, and the kidney only secondarily He had found that the cases in this class that were likely to do well after nephropexy were those that were benefited by rest in bed and were made worse by exercise In the cases that showed nerve symptoms we were on even less firm ground If we set aside those cases where pain definitely arose in the kidney, there was a large class of cases with movable kidney and a varying degree of neurasthenia It was the practice of some surgeons to operate on these cases and to claim success in the treatment It was the experience of others that operation in these cases was unsatisfactory, since the patient either retained all her symptoms or they recurred after a short period of time His views coincided with the latter For one success in a neurasthenic we saw many failures, and he believed that it was very rare for the symptoms to be abolished permanently The test of rest might also be applied here but it was not so reliable in this class When we went a step further and recommended as some surgeons did, the operation of nephropexy as a cure for insanity, he confessed that he had had no experience in such cases II The second cause of failure in the results of the operation of nephropexy lay in the method of operation If one could judge by the numerous operations that were described for fixing the kidney the attention of the profession appeared to have been principally focused on this aspect of the question There were two questions that surgeons should seriously consider (1) Did they wish to fix the kidney absolutely or did they want to retain a certain degree of mobility of the organ, and (2) Were they correct in ascribing to low fixation the cause of their failures? First, in regard to absolute fixation A kidney stitched high up under the diaphragm was not fixed, a kidney, the lower pole of which rested upon a shelf of peritoneum or fibrous tissue was not fixed If nephropexy was done the object should be to fix the kidney completely If any movement was allowed it was impossible to control the amount of movement or to be certain that the movement would not take place in some unexpected direction which would throw a strain on the vascular pedicle or the ureter and thus perpetuate the symptoms In order to carry this out the muscles of the posterior abdominal wall should be prepared by dissecting away the loose areolar tissue fat and muscular sheath and in order to do this a four or five inch incision was necessary Only the posterior surface of the kidney should be stripped of its capsule The anterior surface should not be stripped, for the result was adhesion to the duodenum and colon, and from what he had already said this would be seen to be undesirable. Secondly, in regard to position. Most of the evidence he had seen produced to show that the low position of fixation was the cause of failure in some cases had been of the most flimsy character. So long as there was no dragging of the vascular pedicle and no twisting or other obstruction of the ureter—both of which could easily be guarded against—he saw no reason to believe that a kidney fixed lower down than its normal position need give rise to symptoms. If the kidney lay internal to the outer border of the quadratus lumborum there would be no danger of painful pressure by the clothes. If it was stitched to the lateral wall of the abdomen it might be in danger of being nipped between the ribs and iliac crest, as one author stated, but surely no reasonable surgeon would care to stitch it in this position. He had no objection to placing the upper stitch through the interspace above the twelfth rib. It had been urged against this that the pleura might be injured and that the mobility of the rib loosened the kidney. He had not seen any harm to the pleura result from such a suture. The twelfth rib was fixed, it did not move with respiration, being held rigidly down by the arcuate ligament.

Mr. WILLIAM BILLINGTON said that during the past nine years he had operated on upwards of 500 patients with nephroptosis, and had performed nephropexy about 800 times, both kidneys being dealt with at the same time in a majority of the cases. Careful records of his patients had been kept, and as only about 25 per cent. were hospital cases, it had been easier than usual to keep in touch with their subsequent progress. The operation performed was that described by him in 1907.[1] It had proved so satisfactory that no essential modification of the technique had appeared to be advisable. In his series there had been four deaths, an operative mortality of less than 1 per cent. To his knowledge only one kidney had broken loose again, and with the exception of one patient in whom a small hernia developed in the scar, and two or three who had subsequently suffered from pain in the back, there had been no unpleasant sequelæ. In estimating results several points had to be attended to and a distinction drawn between surgical failures and failure on the part of a successful operation to confer benefit on the patient. A successful operation was, of course, one which efficiently and permanently anchored the kidneys in their normal position and was free from unpleasant sequelæ such as pain, weakness of scar, persistent sinus, &c. Only when such surgical success had been obtained was it fair to estimate the value of the operation therapeutically. At this point he would emphasise the absolute necessity, if satisfactory results were to be uniformly obtained, of replacing the kidneys as nearly as possible in their normal position. He fully endorsed Goelet's statement that a kidney fixed in an abnormal position frequently caused more trouble than when it was freely movable. In estimating the results of nephropexy as regarded general health and working efficiency, he thought that we must clearly realise that when the operation was performed for other than local symptoms it did not make the patient well, but only made it possible for her to get well. Time and treatment on ordinary lines were essential before full restoration to health could be obtained. He claimed that in a very large percentage of properly selected cases nephropexy converted a previously incurable patient into a curable one. In the absence of definite local symptoms he never advised operation until satisfied that ordinary treatment had had a fair trial and had failed or had been followed by rapid relapse. Much unfair criticism of nephropexy had resulted from (1) failure to test the surgical success of the operation before judging of therapeutic results; (2) failure to realise that operation must be followed by careful and prolonged after-treatment; (3) failure to allow of a sufficient interval between the operation and the time at which it was safe to judge of its effects—for patients who had suffered for years from functional troubles and neurasthenia an interval of at least one year was essential before the full benefit could be expected; (4) the selection of unsuitable cases for operation. If the patient was to be made into a normal person he must at one time have been normal. In other words, the operation would not make a congenital degenerate normal. As to results, in his own series of cases he had made two different investigations: Two years ago for the purpose of an address before the Chicago Medical Society he inquired into the condition of 100 consecutive cases, Nos. 151 to 250 in his series; one full year of time elapsed in every case between the operation and the inquiry. He was successful in obtaining information about 87 of these patients, and from this he found that about 60 per cent. were well in the sense that they were leading ordinary lives and did not need medical attendance; 20 per cent. were considerably better; 10 per cent. were better; and 10 per cent. were no better. To test these results, on being asked to take part in this discussion, he submitted the following questions to 11 practitioners, 70 of whose patients he had operated upon: 1. Had the operation been a surgical success—i.e., had it efficiently and permanently anchored the kidneys and had it been free from unpleasant sequelæ? 2. Had the general resulting benefit justified the operation? His reason for doing this was that he believed that the medical man who had known the patient beforehand and had had charge of her afterwards was best qualified to judge of what the operation had achieved. In order, also, that an opinion should not be bas upon too limited an experience, no practitioner was writt to who had not observed at least three cases. His very be thanks were due to these practitioners for the great ca they had taken in confirming general impressions by actual seeing or writing to their patients before answering h inquiry. A summary of the replies received was contain in a printed sheet he distributed. In a few words, it inc cated that in all the 70 patients the operation was a *surgic* success; in only one case, that of a lady who had pain her right side, was there any mention of after-trouble. the general benefit that had resulted, only 5 cases we reported as failures, while many were described as havi been changed from chronic invalids into absolutely norm people. One final word as to the result of nephropexy mental disease. He had operated upon about 30 lunatic 50 per cent. of whom became sane subsequently and ha remained so. Some of these patients had been operated up seven or eight years ago. The results in some of these cas had been observed by Dr. A. Miller, superintendent of t Warwick County Lunatic Asylum, whose general view of t question was contained in the letter in which he answere Mr. Billington's inquiry and which was circulated. Recent at his request Mr. Billington had operated upon two patien under his personal care. One of these was now well an the other rapidly improving.

Mr. SEYMOUR G. BARLING said that he had operated upo about 20 cases of this condition. He always selected thos in which there was a definite lumbar pain or renal symptoms No success attended the operation if general symptoms alon were present.

Mr. HAROLD GARDINER presented the statistics of such cases as had been operated upon at Guy's Hospital for the four years 1909–12. There were 26 operations; 21 patients were relieved; 5 were not completely relieved. The results given, however, were only those within six weeks of the operation. The usual procedure was a simple stitching of the kidney to the posterior abdominal wall, but in a few cases the kidney was slung to the twelfth rib. Under both procedures the results were approximately the same.

Mr. H. BLAKEWAY summarised the results obtained at St Bartholomew's during the same period. 62 patients had been operated upon, 59 female and 3 male. In 43 the right kidney was affected, in 9 the left, and in 10 both were movable. In only two had the operation been performed on both sides. In nearly all the kidney had been simply sutured to the posterior abdominal wall, but in a few also attached to the last rib. All were selected cases. The ages varied from 18 to 54 years. The duration of the symptoms covered periods up to 12 years. He had written to all the patients, had seen 14, and traced 21 by letter. One had died, 26 were not traced. The one fatal case was a woman of 33, who contracted pneumonia and died four months later from chronic interstitial pneumonia Post mortem it was found that the kidney had not been fixed in a normal position. The results were satisfactory in 22, unsatisfactory in 12, and successful on one side in 1. Of the 14 seen, 6 were satisfactory as regards symptoms, but in 2 of these the kidney was still mobile; 8 were unsatisfactory. In all these 8 the kidney was movable, except in 1, in which it was fixed.

---

[1] Brit. Med. Jour., Nov. 27th, 1907.

Mr. RAYMOND JOHNSON read the statistics which had been obtained from St. Thomas's and St. George's Hospitals for cases operated upon during the same period. At St. Thomas's Hospital 53 had been operated upon; 32 of these had replied to inquiries, and the results were stated as follows: good, 16; fair, 4; poor, 2; temporary relief, 1; failure, 9. At St. George's Hospital 24 patients had been operated upon. Eight of these had returned for examination when requested; 3 were worse; 1 was much the same as before; 3 were slightly improved; 1 had completely recovered. The kidney had remained absolutely fixed in 1 only.

Mr. A. E. JOHNSON said that a mechanical cure was often more difficult than was supposed, and that all movable kidneys were not capable of fixation to the last rib. He showed pyelograms to illustrate this point. He thought that it was essential to obtain exposure of the pelvis and upper part of the ureter. The kidney should be fixed as high as possible and a bed should be prepared for it.

The PRESIDENT, in concluding the discussion, pointed out that there was no great variation in the results obtained from the different sources. The number of operations for this condition was probably decreasing in London. He had been struck by the large difference between the records of Mr. Mills and Mr. Billington, and as an explanation of this had been impressed by the point which Mr. Billington made of the importance of after-treatment, which was more readily procurable in private cases. The question occurred to him as to how far the after-treatment itself produced the results. He had not been in the habit of fixing the kidney so high as others claimed to do, and questioned the need for such high fixation. He did not think that an absolutely straight ureter was essential.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Exhibition of Cases and Specimens.—Vaginal Epithelioma treated by Radium.—A Case of Double Ovariotomy.—Genito-mesenterio Fold of Peritoneum.

A MEETING of this section was held on Jan. 8th, Dr. W. S. A. GRIFFITH, the President, being in the chair.

Mr. GORDON LEY showed a specimen of Fatty Change in a Fibromyoma of the Uterus. The specimen had been removed from a patient 54 years of age. The tumour had given rise to hæmorrhage, and the uterus was removed for that reason. The tumour lay in the posterior wall of the uterus. It was encapsulated, and appeared to be a fibromyoma with yellow streaks and yellow homogeneous areas scattered throughout it. Microscopically it showed a fibro-muscular tissue surrounding numerous spaces containing fat. There was no degeneration of the cell elements. Mr. Ley pointed out that the fat was situated in the cells of the connective tissue, and that the globules of fat were large contrasting with the small fat globules seen in the muscle cells in calcareous impregnation and hæmorrhagic necrosis of fibromyomata. He was of opinion that the tumour was either a condition of fatty metamorphosis of the fibrous stroma of a fibromyoma or a fibro-myo-lipoma. From the arrangement of the fat in the tissue and from the absence of young fat granule cells, he concluded that the former interpretation was probably the correct one.—The specimen was referred to the Pathological Committee, who gave it as their opinion that the tumour was a fibromyoma which had undergone fatty degeneration.

Dr. T. W. EDEN showed a case of Chorion-Epithelioma of the Uterus with Bilateral Lutein Cysts of the Ovary. The case occurred in a married woman, aged 27, who was admitted to the Chelsea Hospital for Women. The uterus was considerably enlarged, and after some days the cervix was dilated on account of hæmorrhage and the uterus evacuated of a well-marked hydatidiform [illegible] time there was [illegible] fundus, but it [illegible] patient had lost very considerably. Convalescence was normal. She was then sent to a convalescent home and requested to report herself later. Six weeks afterwards she returned to the hospital and was examined. The uterus was normal, but there was now a soft swelling in the region of the left ovary. There was no discharge from the uterus. A fortnight later the swelling in the left ovarian region had increased considerably, and a smaller cystic mass could be felt on the right side which was not detected at the first examination. Abdominal section was performed and two simple ovarian cysts found, together with a somewhat irregular uterus. Supravaginal hysterectomy was performed, and on opening the uterus masses of soft red growth were found. Sections showed typical chorion-epithelium deeply invading the uterine wall. Lutein cysts were present in the ovaries. The operation, which was performed two and a half years ago, was successful, and the patient had had no return of the disease up to the present time. Dr. Eden remarked on the total absence of hæmorrhage or discharge after removal of the vesicular mole, although a malignant growth was present in the uterus. Attention was drawn to the rapidity with which the ovarian cysts grew, and to the complete cure by operation which had resulted.—Remarks were made by Dr. WILLIAMSON and Mr. MALCOLM.

The PRESIDENT reported a case of Primary Epithelioma of the Vagina treated by Radium. The patient, aged 67, had had one child at 30; no miscarriage. Menstruation always scanty; ceased at 50. Health generally good, but had recently suffered from glaucoma and cataract in both eyes. Weight average. October, 1912: Mucous leucorrhœa first noticed, sometimes tinged with blood, but there had been no hæmorrhage or any pain. June 3rd, 1913: Examined under anæsthetic by Dr. Griffith, who found a warty papillary growth of the posterior fornix about 1¼ in. in length by 1 in. in breadth, apparently involving the whole thickness of the thin senile vagina, but the rectal wall was quite free. The cervix was senile and healthy. A portion was removed and found to be squamous-celled epithelioma. Treatment by radium by Mr. Hayward Pinch at the Radium Institute: June 16th, 25 mg., screen 1 mm. silver, 6 hours; June 17th–20th, 50 mg., screen 2 mm. lead, 6 hours each day; July 25th, Mr. Pinch found that the greater part of the growth had disappeared, leaving a small patch of the size of a sixpence, and gave another course of radium; July 25th–29th, 25 mg. radium, screen 1·5 mm. lead, each day for six hours; Oct. 14th, Dr. Griffith examined and found no trace of disease, the vagina was smooth and soft, but a little more contracted than in June. Dr. Griffith reported this isolated case for two reasons—because primary epithelioma of the vagina was a comparatively rare disease, and because of its anatomical relations, treatment by operation was not very satisfactory, whether by partial excision, as in Dr. C. H. Roberts's case, by excision of the whole vagina (Olshausen), or by excision of the vagina and uterus (Amann). He hoped to be able to report the further progress of his case to the section, and suggested that all gynæcological cases treated by radium, and of which accurate details were obtained, should be reported. References were then made to the literature of the disease.—Remarks were made by Dr. H. MACNAUGHTON-JONES, Dr. H. RUSSELL ANDREWS, Dr. G. BLACKER, and Dr. CUTHBERT LOCKYER.

Dr. RUSSELL ANDREWS brought forward a case of Hæmatometra with absence of the upper part of the vagina. The patient, aged 22, who had never menstruated, complained of abdominal pain recurring every month for the last eight years. For the last few months this pain had been sufficiently severe to keep her in bed. For a long time—she did not know how long—she had had a tender swelling in the lower part of the abdomen. This swelling reached about three inches above the pubes. The external genitals were normal, but the vagina was not more than an inch long. On rectal examination a tumour, the size of a large pear, could be felt in the position of the uterus. No distinction between body and cervix could be made out. The abdomen was opened, and the uterus, which was five inches long, distended with blood, was removed, together with a left-sided hæmatosalpinx and small ovarian tumour, the right ovary, which was normal, being preserved. The patient made an uninterrupted recovery. No trace of the external os could be found, and the vagina seemed to be completely absent except for about an inch at the lower end. Dr. Andrews considered that the removal of the hæmatometra and hæmatosalpinx by the abdomen was better treatment than drainage from below, with an attempt at making a new vagina. The operation of grafting would be a very difficult one in a case where the upper part of the vagina was wanting.—Remarks were made by the PRESIDENT.

Dr. CUTHBERT LOCKYER introduced a case of Double Ovariotomy with unusual post-operative phenomena. This case occurred in the practice of Mr. C. Hamilton Whiteford, of Plymouth, who performed the operation, and whose clinical account of the case Dr. Lockyer read in full before the society. The patient was aged 78, and in August, 1910, Mr.

Whiteford operated for a strangulated right femoral hernia. The sac was so badly infected that the pelvic colon had opened and drained through the lower border of the right rectus muscle. The patient recovered, but was left with the colostomy and a large protrusion in the femoral region. Early in 1913 the lower abdomen began to enlarge, and in June of the same year was enormously distended and presented a fluid thrill. It was decided to make a small incision into the tumour mass, and five pints of creamy dermoid fluid escaped as well as hair. Five hours later an abdominal section was performed, and a large dermoid cyst of the left ovary removed with great difficulty, owing to adhesions. There was a smaller cyst of the right ovary. Both cysts contained more or less typical dermoid elements—hair, bone, skin, &c., together with more solid material of a fibrous nature. The fundus uteri was removed at the time of the operation. The abdominal wound healed well, but on the thirteenth day after a tumour was found in the left iliac fossa. This was incised through the left rectus muscle and simulated a cyst of the left broad ligament. It could not be removed. Five ounces of thin blood-stained fluid were withdrawn on the fifteenth day. The fluid re-collected in the pelvis, and on the twenty-first day 46 ounces were aspirated; on the twenty-eighth day 20 ounces were withdrawn—a total of 51 ounces in three weeks. Examination proved that urea was absent. On the fortieth day thorough drainage per vaginam was established. The patient gradually sank, and died at the end of four months. Post-mortem examination showed small masses of hard white growth in the pelvic floor. The left inferior quadrant of the abdomen was everywhere shut off by adhesions. There was no general hydroperitoneum or visceral deposits. There was no injury to bladder or ureter. Microscopical examination of the portions of the cyst walls showed that the case was one of bilateral perithelioma. The masses in the pelvis, whether secondary or the remains of the primary growth, would account for the curious clinical feature of continuous local secretion of large amounts of fluid by the peritoneum.—The specimens were referred to the Pathological Committee, who agreed with Dr. Lockyer that they were dermoid tumours, in which definite peritheliomatous changes were present.

Mr. DOUGLAS G. REID (Cambridge) read a paper (with lantern slide demonstration) chiefly dealing with the Genito-Mesenteric Fold of Peritoneum, which he had described in the fœtus and demonstrated in adults. He pointed out that the terminal part of the ileum might be connected to the abdominal wall by (1) this fold, (2) the "bloodless" fold of Treves, or (3) adhesions (common both in the fœtus and adult). He discussed the question of intestinal flexures and showed how these might become acute. It was important to distinguish between (1) permanent flexures and (2) those which had no real claim to be regarded other than temporary. The genito-mesenteric fold appeared after the fourth month of fœtal life, was attached along definite lines and at first free as regards adhesions. Later the ileum, appendix, cæcum, &c., might adhere to it, and through it be very closely bound to the right ovary and Fallopian tube. It was very common for the meso-appendix to adhere to this main (genito-mesenteric) fold. This fold was of importance in relation to the spread of infection or inflammation from the bowel to the ovary and tube or in the opposite direction. An important point was the presence of lymphatic nodes in the fold. Surgically the fold was of importance for many reasons. It determined adhesions which, besides lowering the root of the mesentery, would act as barriers restricting the spread of inflammation. It was the commonest cause of a retrocolic position of the appendix. It would complicate operations for the removal of the appendix, &c., produce hernia, displace viscera, and possibly determine strangulation of the bowel. Variations in the position and relations of the appendix at various stages of cæcal torsion were considered and were of importance. The action of the pelvic colon in producing adhesions and obliterating the genito-mesenteric fold was discussed. Thus the fold was not so common in the adult as in the fœtus. The origin of Jackson's membrane was considered. The retro-pancreatico-duodenal fossa and other fossæ, folds, and adhesions were demonstrated, as was the supra-adhesion foramen. Their importance was considered, especially in relation to the formation of "ready-made abscess cavities" and operations upon the stomach. Practically all the points were illustrated with photographs.—Remarks were made by Professor D. WATERSTON and Dr. MACNAUGHTON-JONES.—Mr. REID replied.

SECTION OF OTOLOGY.

Exhibition of Cases, &c.

A MEETING of this section was held on Jan. 16th, Mr. RICHARD LAKE, the President, being in the chair.

Dr. DAN MCKENZIE showed a child, aged 6 years, the subject of Mastoiditis without perforation of the tympanic membrane. A month after the removal of tonsils and adenoids there was swelling in the mastoid region, and on return to hospital the cortical mastoid operation was performed. The mastoid cells were occupied by pus and granulations. At no time was there any discharge from the meatus. Recovery was uneventful.

Dr. MCKENZIE also showed, in conjunction with Dr. BENNETT, a case of Acute Purulent Otitis Media with signs of acute labyrinthitis, in which recovery ensued without operation on the labyrinth. There had been pain and discharge on the right side following influenza, and the cortical mastoid operation was performed a month later, but fever, vertigo, and deafness continued. Three weeks later the wound was reopened, but no fistula into the labyrinth was detected. The temperature fell to normal after the second operation, and the wound slowly healed. Later severe and continuous pain behind the right ear was complained of, radiating to the top of the head and down into the neck. Giddiness ensued on slight movement of the head, and there was nausea, but vomiting and no spontaneous nystagmus. Tests sho absence of hearing in the right ear, and the vestibu reactions were absent. The radical mastoid operation performed, as an exploratory measure, but all the parts w sound and there was no pus. A lumbar puncture yiel normal cerebro-spinal fluid. After a neurological exami tion functional disorder was diagnosed, and a few days lat under strong moral suasion, the pain and other sympt suddenly disappeared. The right ear has remained d and the vestibular responses are negative.

The PRESIDENT exhibited a patient after operat for Aural Vertigo. He was aged 61, and had be totally deaf for three years. The first attack of vert came on seven years ago, suddenly, while he was asle The attacks had since increased in frequency, but had been so severe as the first one. Objects around him appea to rotate in a vertical plane. Unless he kept his eyes s he vomited. He had continuous tinnitus in the left (deaf) ear. His blood pressure was 110. There was Rombergism; his gait was steady, with no deviation and ataxia. No nystagmus in the left eye (the right eye artificial). The operation was easily tolerated.

THE PRESIDENT also showed some remarkable photograp of Sound Waves (taken by Mr. Duddell, F.R.S.). They we waves produced by various agencies, such as organ pipes various shapes, tuning forks, and violin strings. The latt were quite complicated, and the degree of "interference shown in the latter was held to account for the extrem richness of tone given out by that instrument.

Mr. G. J. JENKINS showed a case of Hæmatoma Aur which he had successfully treated by operation. Th patient, a female aged 32, received a blow at night, an next day the swelling involved the whole external surface the cartilaginous part of the pinna, and was the size of a hen egg. That afternoon an incision was made along the margi of the helix. The contents were mostly fluid blood, bu there were some clots in the lower part. The blood extende somewhat into the meatus. The patient's present appearanc seemed fully to justify the course which had been followed.

Mr. SOMERVILLE HASTINGS showed a peculiar case o deafness for the purpose of ascertaining the opinions o members. The general view seemed in favour of it being functional. The Wassermann test proved negative, and various treatments had been without avail.

MEDICAL SOCIETY OF LONDON.

The Pathology of Syphilis.

AT the meeting of this society on Jan. 12th, Sir DAVID FERRIER, the President, being in the chair, Dr. W. D'ESTE EMERY opened a discussion on the Pathology of Syphilis. His paper (a summary of which appeared last week) is published in full in the present issue of THE LANCET.

Mr. J. E. R. MCDONAGH first drew attention to the cause of syphilis, which was, in his opinion, a spore that went through a complete life cycle, forming male and female bodies.[1] As a result of fertilisation of the female body by the male, which was the spirochæta pallida, spores were ultimately formed again. The spores were shown to differ from the other phases chemically, which accounted for the latent periods to be met with in the course of the disease, the syphilitic lesions being due to the activity of the spore in completing its life cycle. The pathology of all the syphilitic symptoms was discussed, and special attention was paid to the pathology of the specific nervous manifestations. Mr. McDonagh considered that the early syphilitic nerve lesions were vascular, giving rise to hemiplegia in the brain and myelitis in the cord, both lesions of the anterior surface. The late lesions were due to direct extension of the organisms from the meninges into the nerve substance, which gave rise to general paralysis in the case of the brain and tabes in the cord, both lesions of the posterior surface. The way the body reacted to the syphilitic organism and how it protected itself against it were next discussed. Mr. McDonagh considered that salvarsan attacked the spirochætæ directly owing to the free OH groups which the organism presented, since it contained in its chemical configuration an unsaturated fatty acid, but that the other phases were destroyed indirectly. Salvarsan he considered to act as an accelerator of the enzyme action with which the serum and plasma cells attacked the leucocytozoon, and this zymotic action was thought to be of the nature of an oxydase. Reference was made to the Wassermann reaction, the luetin reaction, and the tests employed for examining the cerebro-spinal fluid, but since the rationale of the chief tests was unknown Mr. McDonagh thought it wiser to defer discussion till later.

Dr. **PAUL FILDES** said that the effect of treatment upon syphilis, as illustrated by the behaviour of the Wassermann [illegible] to the stage of the disease. In [illegible] might be made negative rapidly [illegible]te syphilis the reaction seldom if ever became negative. Thus it might be said that early syphilis was curable, but late syphilis incurable. This phenomenon was due to the fact that early syphilis was a epticæmic condition, while in late syphilis no spirochætæ were found in the blood stream. Since drugs operated through he blood stream they were unlikely to affect spirochætæ which had already invaded the tissues, especially as the ffect of salvarsan was very transient. It was no longer to e found in the blood after a few hours (McIntosh and Fildes), and therefore it would have little opportunity f destroying spirochætæ which were distant from the essels. It had been suggested that spirochætæ became hidden in gummata and thus escaped, but, on the other hand, gummata were very readily curable. The incurability f late syphilis was due to anatomical, not pathological, causes. There were areas of the body into which salvarsan did not penetrate, in particular the brain (McIntosh and Fildes) Thus any spirochæta situated in the extravascular cerebral tissues would survive in spite of treatment, as in dementia paralytica. Another area which remained unaffected by salvarsan was the aorta Mesaortitis syphilitica was by far the commonest late lesion of syphilis in the post-mortem room (Turnbull and Fildes). The greater part of the aortic wall was non-vascular, and thus the spirochætæ escaped destruction.

Dr. J. **MCINTOSH** said that the difficulty of effecting a cure in the various *manifestations of nerve syphilis* was a well-known clinical fact, but why was this so since all such esions were due to the presence of the spirochæta pallida? Either the spirochætæ had become resistant to the medicament or else they were not reached by it. The first was readily disposed of, as there was no direct evidence in support of the contention. Three years ago, while investigating the distribution of arsenic in the organs of a congenital syphilitic infant who died shortly after salvarsan treatment, he was struck by the fact that no arsenic was present in the brain. An examination of several other brains, both human and animal, demonstrated that arsenic did not get into the brain even after large doses of arsenical preparations had been given. At first Dr. Fildes and he considered that this merely showed that salvarsan did not fix on the brain substance, and was therefore not neurotropic. They, however, had found that salvarsan fixed as readily *in vitro* to the brain as it did to the liver. The failure of the arsenic to reach the brain they considered was due to two causes. 1. The active duration of arsenical preparations in the blood stream was very short, due to its being rapidly "mopped up" by the liver and other vascular organs. *In man, even after a maximum dose of neo*-salvarsan, little or no arsenic was present in the blood after an interval of 12 hours. In fact, a therapeutic quantity was only present for three or four hours. 2. A peculiar anatomical construction of the brain and its membranes, in particular of the capillaries. It had been said that the arsenic failed to reach the brain because it did not gain access to the cerebro-spinal fluid, which was looked upon as the lymph of the brain. They, however, could not agree with this, as it was most unlikely even from its composition alone that cerebro-spinal fluid was a nutritive medium. As regarded the therapeutic effects of Swift's intraspinal injections they had found that the amount of serum injected contained a therapeutic dose of salvarsan, so the curative effect was due to this and not to any syphilitic antibodies.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Jan. 9th, Dr. A. K. Chalmers, *the President, being in the chair.—Dr. Andrew A.* McWhan read a paper on Problems of Rural Housing. He said that the failure to provide a sufficient number of sanitary dwellings for the working classes had been attributed to the indifference or unwillingness of local authorities to carry out the provisions of the Housing Acts, more especially when these involved the possibility of increasing the local rates, and to the difficulty of erecting suitable dwellings at a cost allowing of their being let at a remunerative rental; but in rural districts there were also economic considerations complicated by political opinions, particularly on the land question. In Scotland the problem of reconstruction was complicated by the fact that many rural houses were built of stone and were without damp-proof courses, which on account of excessive cost could not be inserted in existing dwellings. Although the duty of providing houses was cast upon rural authorities it was unlikely that they would carry out that duty without central pressure, and county councils were not likely to be any more active. If the Housing Acts were to be administered honestly and conscientiously by the local authorities and it was found that the cost entailed in housing schemes involved a charge which rural industries could not bear, the solution of the housing problem lay with economists and politicians, and not with sanitary officials.—Dr. W. G. Savage agreed that medical officers of health often found themselves considering the problem from the administrative point of view as well as from the broader aspect in relation to the economic welfare of the country. In his opinion the essential business of the medical officer of health was to carry out his legally prescribed duties and neither to neglect nor to modify them because he considered that to do so would make existing matters worse. It was his duty to ascertain and to represent all unfit houses to his authority. It was for the authority to consider the representation and to decide as to the necessity for making closing orders. The owner of a condemned house should always be supplied with a full list of its defects which when remedied would make the house fit.—Mr. F. E. Fremantle *advocated the provision* of three-bedroom cottages, and considered it should be made illegal for a girl over 6 years of age to occupy the same bedroom with boys or men.—Dr. A. H. Bygott uged the importance of building by-laws and thought that county councils should have the power to make them —Dr John Taylor preferred to see a minimum floor space insisted upon rather than make three bedrooms compulsory. It would be useless to send the housing problem [illegible] it must be dealt with by the central [illegible]ation of a [illegible] powers of a local authority, and should only use them when the latter did not desire to do so.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting of this society was held on Jan. 16th at the West London Hospital, Dr. F. S. Palmer, the President, being in the chair.—Three short papers were read on the subject of Congenital Abnormalities.—Dr. E. Arthur Saunders discussed Abnormalities from the Medical Side.—Mr. N.

---

[1] THE LANCET, Dec. 14th, 1912, p. 1650.

stomach, intestinal mucous membrane, and the kidney.

We have nothing but praise for this monumental achievement on the part of the author. It is far and away not only the best but the most comprehensive book on the subject. We wish most heartily that it may speedily be presented in an English translation. It is well worthy of it. We can but thank Professor Biedl for his own successful labours on the subject and the ingathering, codification, and exposition of the colossal amount of work by the host of other observers whose names and the titles of their contributions make up far more than one-third of the present volume.

Diagnostic Methods, Chemical, Bacteriological, and Microscopical: A Text-book for Students and Practitioners.

By RALPH W. WEBSTER, M.D., Ph.D., Assistant Professor of Pharmacological Therapeutics and Instructor in Medicine in Rush Medical College, University of Chicago, &c. Third edition. London: Henry Kimpton; Glasgow: Alexander Stenhouse. 1913. Pp. 692. Price 18*s*. net.

WE are glad to see that the favourable opinion we expressed of the first edition of this book has been justified by a rapid demand for further editions, and that the author has thus been enabled to keep the book up to date. The present form of the work still justifies the encomiums we originally passed on its completeness and accuracy, and while it is larger by some 50 pages than the first edition, its price has been reduced from 25*s*. to 18*s*.

Additions to its contents include, among others, Tollens's test for glycuronic acid, Hart's for β-oxybutyric acid, and Abderhalden's sero-diagnosis of pregnancy. The author regards Benedict's test as the best for qualitative recognition of sugar in the urine, and Bang's as the most accurate quantitative reagent. The latter seems indeed to be gaining general recognition in laboratory work. Apart from our former criticisms as to the advisability of devoting space in a manual of diagnosis to theoretical pathology such as the causation of diabetes or Ehrlich's theory of immunity, we would suggest that such procedures as the author finds to be of little or no value should be omitted, whereas, on the other hand, when a special manipulation, such as Sahli's method of tying the little india-rubber bags used for his gastric test, is noted as important, it is exasperating to be referred to the original article for guidance. The account of the diagnostic use of tuberculin is particularly meagre. There are fewer misprints than in the first edition, but we notice "oligema" for oligemia, "vesicle" for vesical, and a few more. The blemishes that we have found are, however, slight, and we unhesitatingly commend the book to the attention of laboratory workers, to whom it should prove of the greatest value.

Sciatica: a Fresh Study.

By WILLIAM BRUCE, M.A., LL.D., M.D. Aberd. With notes of nearly 700 cases and 18 plates. London: Baillière, Tindall, and Cox. 1913. Pp. 175. Price 5*s*. net.

THE view that sciatica is essentially a disease of the hip-joint is associated in these days more particularly with the name of Dr. William Bruce, whose writings on the subject are probably familiar to the medical profession. In the present little volume he has amplified his own views and supports them with a very large amount of clinical material investigated in a painstaking manner.

In a considerable number of cases Dr. Bruce says that the muscles of the hip are wasted; there is marked tenderness on pressure over the capsule of the joint; passive movements at the articulation are often limited and cause pain. Taken collectively, these arguments for the arthritic origin of sciatica are, in the author's opinion, very cogent, and he holds that when it is found that a large proportion of cases are due to hip-joint trouble it is philosophical to assume that the remaining cases also belong to the same category. He maintains that other explanations are both hypothetical and insufficient.

We do not suppose that anyone will quarrel with Dr. Bruce's contention of the frequent arthr origin of sciatica; this has long been recognise writers on the subject. If the physician will submit every case of the condition to X-ray exa nation he will be surprised at the frequency which arthritic changes in the joint can be re nised. At the same time, we cannot subscrib the generalisation of Dr. Bruce, that other expla tions are insufficient. Sciatica may be a symp of disease of the cauda equina, of tumours meningitis of the cauda or conus medullaris may complicate a myositis, or may occur as evide of definite neuritis, as, for instance, in diab sciatica. These conditions are not hypothetic their pathology is unmistakable. Some years a we drew attention to a paper by Professor E Petrén, of Upsala, on the relation of sciatica morbus coxæ senilis (unfortunately Dr. Bruce d not refer to this important paper in his bib graphy), in which evidence is adduced to show t it is possible to make a differential diagn between the types of sciatica; and the practitio who may be inclined to be satisfied with the ar ments advanced so lucidly and so cogently b physician of such experience as Dr. Bruce will well to read that article.

Handbook of Sanitation.

By G. M. PRICE, M.D., Director of Investigation, N York State Factory Commission, &c. Third edition. N York: John Wiley and Sons. London: Chapman a Hall. 1913. Pp. 353. Price 6*s*. 6*d*. net.

THIS handbook is primarily intended for sanitar tenement, and other inspectors in the vario United States services, and gives an introdu tion to some of the elements of practical sanita science. It is, however, hardly full enough to serv for English readers as an examination text-boo and as a work of reference it would, we think, hav gained by greater detail in describing matters i which strict attention to exact methods is necessar The examination of drains by the water, smoke and peppermint oil tests, or the procedure to b followed in dealing with offensive trades an nuisances, are instances in point. It is noteworth that Dr. Price, in dealing with public water supplies considers that, whether there is a public water purification plant or not, every individual household should itself be provided with some means of local water purification—a proposition decidedly foreign to British theory and practice.

The chapter on foods has been rewritten and expanded, but the short paragraphs given to the preparation of various foods seem hardly sufficient as a guide to practical food inspection, and are n always strictly accurate. The description of mil

---

1 THE LANCET, May 29th, 1909, p. 1539.

powders as prepared "by slow evaporation of the water of the milk" hardly applies to the usual processes of making dried milk; condensed milk as a rule is very far from being sterilised; and the percentage of cream in milk is not the same thing as the percentage of milk in cream. The proportion of tuberculous milk which owes its tubercle bacilli to infection from the human tuberculous case is so small by comparison with bovine infection that it hardly deserves the prominence which it receives in the text. The distinctions between chilled and frozen meat might usefully have been stated, and the process of curing described under methods of preservation of meat.

An addendum to the report gives a useful set of specimen examination papers set by the New York State and municipal civil service commissioners to candidates for the various sanitary posts. These questions are searching, and some of them—for example, What is a sweat-shop? What would you do on seeing cocoanuts with one eye plugged? In what way would you find out whether a boiled lobster was fit for food?—might be expected to elicit some curious answers.

L'Action Directe sur les Centres Nerveux: Centrothérapie.

Par PIERRE BONNIER. Avec figures dans le texte. Paris: Félix Alcan. 1913. Pp. 304. Price 5 francs.

IT is somewhat difficult to follow the author of this little volume in his contention that the medulla oblongata is the "bureau of works" for the whole organism, and that it is owing to the functional activity of the medulla that every tissue element, every viscus, every mechanism, is what it is and does what it ought to do. Although the author does not, in so many words, specify the exact anatomical relations of medullary centres to the various viscera of the organism, it is probably the autonomic system of which he is speaking and to which he attributes so much. In this respect we feel that the true sympathetic system has been somewhat neglected; certainly its functional activity is of equal importance for the organism.

Assuming, however, the general position, the author proceeds to argue that it is always possible to modify the function of bulbar centres by direct afferent stimuli, the shortest path for which is by the sensory nerves of the nasal mucosa to the ponto-medullary centres of the fifth or trigeminal nerve. We may grant at once that a patient may be roused from fainting or a deeper unconsciousness by cold water thrown on the face, by stimulation of the nasal mucosa with ether or ammonia, by traction of the tongue, and so on. It is, however, a long and uncertain step from this to hold, as the author does, that there are definite points on the nasal mucosa, stimulation of which will have a special action on one or other viscus or bodily system. He makes out a sort of map of the nasal mucous membrane, and by light cauterisation in selected spots he considers that he has cured or relieved such diverse conditions as cirrhosis of the liver, claustrophobia, albuminuria, angina pectoris, exophthalmic goitre, and Little's disease. The author gives a catalogue of diseases in alphabetical order treated by himself by this method, beginning with aboulia and ending with xanthelasma. It is regrettable that any useful elements of therapeutic practice in the method, of which we do not doubt the author has had much successful experience, should be obscured by its exaltation into a panacea for all the ills, organic and functional, to which flesh is heir.

Lord Lister: His Life and Work.

By G. T. WRENCH, M.D. Lond. London: T. Fisher Unwin. 1913. Pp. 384. Price 15s. net.

THIS is an industriously written book putting out the salient points of Lord Lister's great career. The author, having had, we surmise, little or no personal acquaintance with his subject, does not represent the events quite in due proportion, but he has attacked his task with whole-hearted energy, and brings to it the qualities of fluency, and the capacity for arranging the vast stock of material which is the common property in connexion with Lord Lister's life.

It is well known that when the Listerian doctrines were first promulgated they did not receive universal approval from contemporary authorities, and indeed aroused antagonism among many surgeons both at home and abroad. London was perhaps particularly slow to perceive either the value of the work which had already been done, or its immense prospects, although in this connexion we find Dr. Wrench's description of the attitude of THE LANCET misleading. He tries to make us ashamed of our descent from persons who, in the early "seventies," displayed such "silly arrogance" and "inconceivable vanity"—if not of our present existence. Well! well! if that sort of thing, however inaccurate, will help to sell a book which presents Lord Lister as a hero we have no objection to make. But we question Dr. Wrench's wisdom in essaying so large a task as a biography of Lord Lister or an appreciation of his work. For such a task it seems to us can be discharged adequately only by someone having more familiarity alike with the details of the history as they occurred, and with the developments of modern pathology, so far as they derive from, or are connected with, or are independent of, the wonderful exploits in Glasgow, Edinburgh, and London of half a century ago. For example, Dr. Wrench does not appear to us to understand clearly what a modern pathologist means by immunity. For him it seems that destruction of the microbe by chemical agencies, whether carbolic acid or nature's complex products, is the whole objective. He does not comprehend that the use of a vaccine is an attempt to bring antibodies (not antiseptics) made by nature's own methods to the actual parts where microbes are producing their effects by the natural agencies; he does not appreciate in this connexion the limited action of the antiseptic applied externally. The wisdom and philosophy of Lister's methods really require no support, and Dr. Wrench's allusions to vaccines would not enhance Lister's achievements, if anything were wanting to that end. His concluding chapter might well have been omitted.

We do not quite understand the stricture passed upon Lord Lister's "most devoted friends and followers" who "did not become fully imbued with the wonderful simplicity that characterised the master." The cause of these remarks is the form in which Lister's written works appeared five years ago, when a collection of his scientific papers was published in two large volumes by the Clarendon Press. This publication was made at the instance of many men who desired to do some little personal honour to the famous octogenarian on the occasion of his eightieth birthday. The fact that these volumes were large, excellently printed and illustrated, handsomely bound, and distinctly expensive is set down to the "pomp and vanity of man," the vain and pompous people being in Dr. Wrench's mind, we must suppose, those who were responsible for the shape and style in which the volumes were issued. If Dr. Wrench had been familiar with the proceedings in connexion with the issue of those volumes he would have known that Lord Lister himself approved of the format chosen, the size being necessary for the inclusion of some of the illustrations.

We have no doubt that this book will obtain a good circulation, and we would not have it otherwise because of the whole-hearted admiration of Lister which pervades it, and which will be communicated to every reader. But it is not an important or judicious production.

LIBRARY TABLE.

Food Inspection and Analysis. By ALBERT E. LEACH, S.B. Revised and enlarged by ANDREW L. WINTON, Ph.D. Third edition. First thousand. New York: John Wiley and Sons; London: Chapman and Hall, Limited. 1913. Pp. 1001. Price 31*s.* 6*d.* net.—We have commended this book upon two previous occasions, and we can express no surprise that a demand has arisen for a third edition, since it presents an excellent account of modern analytical methods applied directly to the examination of foods and beverages. Considerable revision and extension have been effected in this new edition, this duty having been undertaken by Dr. Andrew L. Winton, chief of the Chicago Food and Drug Inspection Laboratory, Bureau of Chemistry in the United States Department of Agriculture. In spite of the number of new analytical details included, the size of the book has only been increased by 47 pages. Space has been wisely saved by jettisoning those earlier methods of analysis, which are now replaced by more accurate and convenient procedures. The administration of food laws in the United States is conducted on somewhat different and more strict lines than is the system in use in this country. On questions of legal procedure, therefore, the book would afford little help to the English public analyst, but it will give him considerable assistance in regard to laboratory work connected with the detection of adulteration of foods and beverages. The processes described are well up to date, and give evidence of having been submitted to practical trial in the writer's laboratory. Apart from analytical practice, the information which it contains is of interest from a general economic standpoint.

A Handbook of Sanitary Law for the Use of Candidates for Public Health Qualifications. By B. BURNETT HAM, M.D. Brux., M.R.C.S. Eng., D.P.H. Camb., late Chief Health Officer for Victoria, Australia, and Commissioner of Public Health for Queensland. London: Ash and Co. 1913. Pp. 194. Price 3*s.* 6*d.* net.—This little volume has no more ambitious object than the condensation of a very considerable mass of legal matter for the benefit of medical students desirous of taking the Diploma of Public Health. The author claims to have reduced the clauses of the Acts to a simpler and less complex form, avoiding for the sake of his readers the tiresome obstacles to rapid study imposed in Acts of Parliament by cross references. At the same time he has naturally aimed at preserving the legal meaning of the original statutory text, and so far as this object can be attained consistently with extreme brevity, he appears to have succeeded. He has undoubtedly supplied in a very small compass a useful analysis well adapted for the purpose indicated, although those who make use of it must always bear in mind that it is an analysis only, and also that the analysis which they make for themselves from the actual text of the statutes that they have to master will (whenever time is possible) give them the best and most enduring knowledge of the matter to be assimilated.

Studien zur Pathologie der Entwicklung. Herausgegeben von Dr. ROBERT MEYER (Berlin) und Dr. ERNST SCHWALBE (Rostock). Erster Band, erster Heft. Mit 44 Abbildungen im Text und 3 Tafeln. Jena: Gustav Fischer. 1913. Pp. 196. Price 8 marks.—The pathology of development is a territory as yet little explored, and no two better editors could be found to guide and direct us upon a difficult journey. The subjects dealt with are the Methods and Value of the Comparison of Human and Animal Malformations, by E. Schwalbe; Contributions to the Doctrine of Fœtal Diseases of Bone, by H. Hässner; the Biological Relations between Mother and Child during Pregnancy, by Bruno Wolff; Vertebrate Hypermelia, by Dr. Pol; and Heredity of Hypotrichosis Congenita, by Dr. G. Luizenmeier.

The Propaganda for Reform in Proprietary Medicines. Eighth edition. Chicago: The American Medical Association. Pp. 375. Price, paper, 15 cents; bound, 25 cents. *Nostrums and Quackery.* Second edition. Same publishers. Pp. 708. Price $1.50.—The Council on Pharmacy and Chemistry of the American Medical Association publishes various volumes relating to all kinds of organised quackery in medicine. The "Propaganda," a volume of reprints from the Journal of the Association, is in four parts: (1) Council Reports; (2) Laboratory Contributions; (3) Miscellaneous Nostrums; and (4) Miscellany. "Nostrums and Quackery" consists also of reprints from the Association's Journal, and deals with various advertising specialists, mail order medical concerns, mechanical fakes, medical institutes and advertised cure-alls, cough medicines, food tonics, habit-forming nostrums and "cures" for headache, kidney troubles, constipation, rheumatism, sea-sickness, cancer, consumption, drunkenness and drug habits, "female complaints," obesity, rupture, diabetes, and so forth. Illuminating information can be obtained from these volumes about most, if not all, of the more dangerous of the patent remedies.

Australasian Medical Congress: Transactions of the Ninth Session, held in Sydney, N.S.W., September, 1911. F. ANTILL POCKLEY, M.D. Edin., President. 2 volumes. Published under the direction of the Literary Committee. Sydney: William Applegate Gullick. 1913. Pp. 1346.—Our Australian correspondent referred at some length to this congress in THE LANCET of Nov. 18th, 1911, p. 1440. The present volumes contain the communications in full with abstracts of the discussions. Even a mere enumeration of the papers would require more space than we can afford. Suffice it to say that the papers cover almost the entire field of medicine and medical economics.

Biomalz

(Biomalt),

a Food which is very extensively recommended by Medical Men abroad, is prepared from high-class barley-malt, with the addition of calcium-glycerine-phosphate, and is now obtainable in Great Britain at all Chemists and Druggists. Samples and literature may be obtained post free from the Wholesale Depot of "Biomalz," REGENT HOUSE, KINGSWAY, LONDON, W.C.

THE LANCET size, 200 pp., paper cover, price 5s., by post 5s. 4d.

THE LANCET AND THE HYDERABAD COMMISSIONS ON CHLOROFORM:

[illegible] to investi- [illegible] and other Reports of [illegible]

The whole comprises a valuable record of cases and Experiments such as, it is believed, is not to be found in the pages of any other single work.

The Lancet Offices, 423 & 424, Strand; and 1 & 2, Bedford-street, W.C.

Crown 8vo, price 6d., by post 6½d.

DIFFICULTIES UNDER THE INFECTIOUS DISEASE (NOTIFICATION) ACT, 1895:

Being a Reprint of the Series of Articles on this subject which appeared in THE LANCET. Doubtless many will care to possess, and will find extremely useful, an elucidation of the principal points on which doubts and difficulties have arisen, and the various decisions and official interpretations which have been given with regard to them.

The Lancet Offices, 423 & 424, Strand; and 1 & 2, Bedford street, W.C.

TO ADVERTISERS.

The Manager begs to intimate that in order to meet, to some extent, the demand made by Advertisers for "position" pages—in which respect THE LANCET *will still continue to be deficient as compared with most weekly Journals—the position occupied by this and the following page has been created, and will be known as "Preceding Leader."*

Heavy types or heavy blocks will not be eligible for this position, nor can any border rules be used.

The price will be £12 net per page and pro rata, with a minimum space of one-eighth of a column (=1⅛ in., 15/-), and proceeding by one-eighths (the usual two columns to a page), and consequently there will not be any serial discount.

It will not be practicable to accept any conditions calling for space on either page in particular, or for any precise position on the page, and successive weekly insertions cannot be guaranteed.

(Gold Medal, International Congress, 1913.)

"TYLCALSIN" & "TYLLITHIN"

(Reg. Trade Marks; Patent).

In treatment of Influenza, Catarrhs, Neuralgia, Rheumatic Affections, Sciatica, and wherever prompt Analgesic effect is required.

1 oz., 2/-; 8 oz. package, 15/8; 16 oz., 30/8

Tylcalsin Tablets ... 36 2/6 | Tyllithin Tablets ... 20 1/6

The British Medical Journal (14th June, 1913, p. 1277), says:—"Tylcalsin and Tyllithi are very readily soluble in water, and their solutions rapidly undergo hydrolysis in th presence of alkali, showing salicylate in considerable quantity after a very short ti The advantage presented by these salts over acetyl-salicylic acid is, of course, the greater solubility, favouring rapidity of action."

ELIXIR & EMULSION OF LECITHIN

Palatable preparations of the nerve nutrient Lecithin.

MILK AND GLYCEROPHOSPHATE

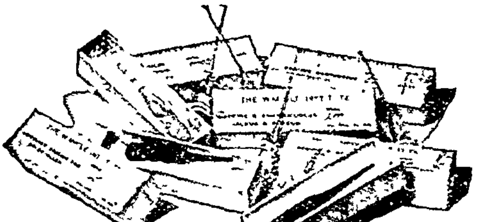
A useful combination containing ALL THE NATURAL SOLIDS OF FRESH MILK (including all its Cream) and CALCIUM GLYCEROPHOSPHATE.

AS A NERVE NUTRIENT.

Bottles ... ... 2/- each.

SENSITISED VACCINES.

The latest Development in Vaccine Therapeutics.



These Vaccines differ from the ordinary variety in the fact that in the course of preparation, the specific antibodies contained in the corresponding antisera are combined with the bacillary substance.

The Wimpole Institute is making a speciality of Sensitised Vaccines, and has succeeded in preparing them of the following bacteria:—

Staphylococcus Albus
Staphylococcus Aureus
Streptococcus
Pneumococcus
Gonococcus
B. Coli
B. Typhosus and
B. Influenzæ.

The Special Advantages possessed by Sensitised Vaccines are that they:

1. Produce a much more speedy rise in immunity.
2. Cause very little local or general reaction.
3. Are quite incapable of injuring the patient.

The resultant immunity is, however, not so great in degree or in permanence; the administrations have, therefore, to be made more frequently and in greater dosages.

Special Indications for their use:

1. The presence of an epidemic when rapid immunity is desired.
2. Systemic and very acute infections, especially if toxæmia be marked

PRICES ON APPLICATION.

The Public Interest in Medicine.

ALLUSION has been made in these columns recently, and on more than one occasion, to the fact that the number of persons taking an intelligent interest in medicine grows apace; and, although this situation is full of promise, it is not without its risks. For how is the exact position of scientific medicine to be interpreted to the public with regard to any particular question in such a way that the message shall be alike sound pathologically and intelligible to those without technical training? Brief expositions of surgical achievements or medical aspirations—whether written in the definitely professional medical papers, where on occasions and for reasons they may sometimes be found, or in the lay papers, where they have become so common as to be almost of daily occurrence—are not yet so useful to the public as undoubtedly they will be when a larger number of persons receive as a matter of course some scientific training. At the present time there is no doubt that articles containing medical information or theorising, intended for public consumption, while the details of clinical treatment are under consideration, too often lead to the drawing of incorrect conclusions by the readers.

One reason for this is the necessity on the part of the journalistic author to say something definite, and this leads to statements which, however accurate taken by themselves, can with a very little gloss be made misleading to the public. Let us take as a concrete example any article upon medical treatment in a daily paper, founded upon undeniable information received from a medical man. The medical man, speaking quite honestly from his own experience, and having had successes in certain directions, communicates his results to a lay journal in response to an invitation to do so. We are not now commenting upon the propriety of the action. He may be supplying arguments on which there will be founded a charitable appeal, and how generous the support thus extended to medicine is we all recognise gratefully. Anyhow we are assuming that the medical man is acting with the single-minded desire to give to the world something the world would be the better for knowing, and that similar motives prevail with the newspaper. Neither the medical man nor the journal which obtained his assistance would be likely to claim epoch-making discoveries for the source of information; error arises in quite a different and perfectly honest manner. And in this way. The medical informant, knowing the work in the particular direction that has gone before, *and possibly able to appreciate the* kind of way in which it is going to develop, portrays the success of his particular procedure as one step in a long story. When the article appears in a lay paper, where there is no room to tell that story, isolated episodes wear, without any intention on the part of anyone, the appearance of important departures, with a promise of still greater developments for which no grounds are usually given, however solidly they may exist. Faithfully reported information, acquired from honourable sources and disseminated for the good as well as for the interest of the reader, may thus misrepresent pathological events by changing their proportional significance. So it can be when a responsible and well-informed lay organ is in question. But when less scrupulous newspapers seize on such events real harm is done. A new cure for "dumb ague," or "Stevenson's disease," is announced on the strength of a statement by one doctor that one procedure in one set of circumstances has been found useful. An imposing amount of attention is devoted to the past history and present exploits of the unfortunate practitioner whose work is now hailed as pioneer, while the medical profession is either puzzled by the praise bestowed on it for discoveries that have not been made, or irritated by the criticisms of those who reproach the profession for not having made these discoveries before.

It is not more medical learning which the public have to acquire before they can benefit by the dissemination of medical knowledge in lay journals. It is to a wider appreciation of scientific principles that we have to look for the remedy. New ideas of freedom and culture followed upon the *dissemination* of the teachings of Greek and Latin literature at the Renaissance, but the spirit of the new learning was not made more influential by the debates of philologists. What is wanted is a familiarity with the scientific aspect of things, which can only be acquired by a general grounding in natural philosophy. If the public were better prepared in this way they would be able to appraise medical achievement with more exactness.

◆

A Research Institute in Edinburgh.

AT the annual dinner of the Royal College of Physicians of Edinburgh, which was held at the College on Friday last, Jan. 16th, an informal revelation was made of a great scheme now imminent for the foundation in Edinburgh of a research institute—an institute as a memorial to LISTER, who did so much of his wonderful work both as Professor of Clinical Surgery in the University of Edinburgh and as an extramural teacher. The scheme, as partially revealed at the dinner by Sir WILLIAM TURNER, the Principal of the University of Edinburgh, with the sanction in certain directions of the chairman, Dr. GRAHAM BROWN,

Annotations.

"Ne quid nimis."

THE LATE LORD STRATHCONA.

WITH the death of Lord Strathcona and Mount Royal passes a great man, one whose memory will be held green by all members of the medical profession. Not only will they share with their fellow citizens in admiration for a man of indomitable courage and perseverance and inflexible uprightness, but still more, as members of a profession to which the subjects of education, the extension of knowledge, and its application to the relief of suffering are of paramount importance, they will feel grateful for his warm sympathy and munificent material support. Elsewhere eulogies on Lord Strathcona's patriotism and public services are being freely rendered. We may be pardoned for confining ourselves to a reference to the special qualities that should endear his memory to the medical profession. Let us recall that at the last International Medical Congress he showed his interest in and respect for medicine and the medical profession by giving a magnificent evening party at the Royal Botanical Gardens, which was attended by some 5000 members of the profession and their friends. This enormous number of guests was received individually by himself and by Lady Strathcona, whose loss some two months later was a blow from which he never fully recovered. His generous support of education and philanthropy is evident in the fact that his endowments to the McGill University amount to some £110,000; that, with Lord Mount-Stephen, he celebrated Queen Victoria's Jubilee in 1887 by providing £200,000 to build the Victoria Hospital at Montreal, which the same munificent donors later, in 1896, endowed with a further £160,000; that in 1896 he built and endowed the Royal Victoria College for the Higher Education of Women, at a cost of another £200,000; and that during his lord rectorship and subsequent chancellorship of Aberdeen University that ancient seat of learning benefited repeatedly by his munificence. Such being the worth and munificence of the man, well known throughout the world, the hall marks stamped on him sink into insignificance. Still it is a satisfaction to know that public and academic recognition was freely forthcoming. It will be a further source of gratification to the medical profession that his peerage is now intimately connected therewith, for by a special remainder it passes to his only daughter, the wife of Mr. R. J. Bliss Howard, F.R.C.S., of London, and her male heirs.

THE EARLIEST PRINTED MEDICAL BOOKS.

Sir William Osler is the first medical president of the Bibliographical Society, and it was fitting that he should choose for the subject of his presidential address before that society on Monday last the earliest printed medical books and the influence of the art of printing upon the art of medicine. Sir William Osler is well known as a lover and collector of ancient volumes, and those who attended the society's annual meeting not only heard an attractive discourse, but were also able to see and handle a number of early medical works and facsimile pages, arranged round the lecture room in chronological order. The period chosen for discussion and illustration was from the dawn of printing to the year 1480 A.D. This was the century of Columbus and Guttenberg, but, as the president put it, it was a sterile medical century. Hence the earliest printed medical works are of greater typographical than scientific interest. At that time the Arabian medical authors, notably Avicena, completely dominated medical thought and practice, and humoral pathology held the field; no work of Hippocrates or Galen was printed up to 1480, and only one commentary of each was published in type. The earliest known piece of medical printing is a single sheet medical calendar for popular use, printed at Mainz about 1457 by the printer of the 36-line Bible. Many such so-called calendars were circulated at this period, and their teaching is strongly flavoured with astrology. In considering the influence of Arabian medicine (which left a more permanent mark upon pharmacy than upon medical practice) Sir William Osler remarked on the enormous popularity of the writings of Avicena, whose sway lasted for centuries. His works were frequently reprinted from 1472, and innumerable commentaries appeared. In 1470 was published the first dictionary of treatment in one volume, the kind of thing, said Sir William Osler, which medical men with a liking for penny-in-the-slot treatment still call for and obtain; but the first work of this sort was also the best, for it gave many more drugs for each disease than any later rival. Speaking of the fascination of early volumes and the interest which the bibliophile finds in the biography of books, the president reminded his hearers that all books can be dated by the expert, who can tell almost at a glance from internal or external evidence when they were written and when printed. So too, he added, he himself could place in its correct decade any leading article on pathological medicine which had appeared in THE LANCET since, say, 1860. With this personal touch we must leave the recollections of a delightful and instructive afternoon.

RINGWORM CURES.

FROM time to time cures for that intractable disease, ringworm, are published, and it is usually claimed by those who devise these cures that they are infallible, though no such claim is made in this issue of THE LANCET by Dr. C. Hughes Foley in a clinical note. The disease shows little tendency as yet to diminish in frequency, in spite of the far more general and drastic attempts to eradicate it. The elaborate method of treatment by the X rays holds the field, though the "cures" under much more simple methods multiply. It is certainly curious that some of these rapid methods of cure of ringworm emanate from those who will frankly confess that they have not a very large experience of the disease, and not from dermatologists. At least one cause of this situation is undoubtedly the fact that there are various forms of ringworm, and that some of these are much more easily cured than are others. Dr. Foley's interesting account of a new and simple treatment of ringworm is a good example of this, for the author tells us that in most of his cases the patients were infected by handling cows and calves. The treatment consists in painting the part with a strong solution of iodine and then spraying with ethyl chloride, and we congratulate the author on its efficacy. But we must remember that the ringworm which most commonly affects cows and calves is due to the Megalosporon ectothrix, and that this is the form of spore which is most readily killed. We welcome the contribution, for it may be that the method our correspondent describes may prove efficacious in other and more obstinate forms of the disease, but the evidence at present available is insufficient.

KITCHEN PHARMACOLOGY.

THAT certain articles of food commonly used in the daily dietary possess a medicinal value becomes evident when we review the number of plants or vegetables which are included in the list. It is erroneous to suppose that all the articles which go to make up a meal serve merely as nutrients, for when the peculiar composition of some of them is considered there will be found principles present of the nature of medicines. It is not improbable that amongst these constituents are some which are entitled to rank as active principles in the same way as are the principles found in the drugs of the pharmacopœia. It must be admitted, however, that the pharmacology of vegetables has not received the scientific attention which has been given to drugs, and many medicinal virtues which are claimed for certain vegetables rest upon tradition rather than on laboratory inquiry. The fact, however, remains that definite principles do occur in many articles used for food, and that it is probable that they possess accordingly a pharmacology of their own, apart altogether from the question of their rôle as nutrients. To give some illustrations, claims have been made in favour of a medicinal action exercised by the onion, leek, or garlic. Onions eaten at night, said Frank Buckland, are soporific and promote sleep. They also are known to have a diuretic action and to produce perspiration. Amongst other things they are many a housewife's remedy for coughs and colds and a help to gastric digestion. The pharmacology of the onion probably rests chiefly on the presence of a powerful sulphur oil—allyl sulphide—which has marked stimulating properties. Onions also are credited with being useful in allaying the pains of rheumatism, and it is interesting to remember the use by medical men of sulphur in some form or other in that disease. The turnip, parsnip, and swede contain a peculiar oily principle which may account for their traditional value as an aperient and diuretic, while their juices are an old country remedy for coughs and hoarseness. The presence of starch and sugar would hardly account for these properties. The potato, of course, possesses a decided nutritive value, but it also contains principles, amongst which is solanin, that are credited with diuretic and aphrodisiac properties. The common cabbage is redolent with a sulphur compound which may possibly account for the value attached to it in scurvy and scrofula. Spinach is a well-known laxative—a property, however, which may be ascribed to the fine indigestible fibre which characterises it. There is present also a peculiar principle as well as a quantity of iron in organic form. The tomato exercises medicinal effects which are not completely explained by the presence of alkaline salts. There is a principle present which when taken in a concentrated state produces salivation and a free stimulation of the liver. On this account the tomato has been called vegetable mercury, and an official tincture is prepared in America. Carrots have a similar action, and form a considerable part of the meals at certain health resorts in the belief that they materially-assist in the treatment of derangements of the liver and of the biliary processes generally. As a dressing carrots have been used to mitigate pain and to sweeten surfaces. The vegetable contains a definite principle, carrotin, and a volatile oil which may possess properties that have supplied the traditional curative qualities. The list could be extended, but the foregoing examples serve to show that we may reasonably expect a definite medicinal action resulting from the ingestion of certain vegetable foods. It is also apparent that this action may be related to the definite principles which are known to exist in many of them, and so the kitchen may reasonably be rated as, to some extent, a dispensary of medicines.

BURNS OF THE EYE DUE TO THE CONTENTS OF GOLF BALLS.

IN the *Journal of the American Medical Association* of Dec. 27th, 1913, Dr. H. Lowell has called attention to the serious injuries to the eye, resulting in loss of vision, which may be produced by the contents of a golf ball. During the last few years such cases have been reported from all over the United States. A child finds an old golf ball with its covering partly removed. He removes the rest of the cover and rubber, and then comes on the core, which he bounces till it bursts or cuts it open with a knife. The contained fluid spurts over him and into his eyes. This fluid is highly caustic. Analysis shows that in some cases it consists of barium sulphate, soap, and free alkali; in others it is a solution containing zinc chloride. The following are some examples of the results. A girl, aged 9 years, was admitted into the Massachusetts Charitable Eye and Ear Infirmary on Sept. 1st, 1911. Three days before while cutting open the core of a golf ball the contents spurted into her left eye. On examination there were much chemosis and swelling of the conjunctiva. The lower fornix was practically obliterated and the cornea was diffusely whitish and hazy. On Sept. 3rd there was hypopyon filling a third of the anterior chamber and the Saemisch operation was done. On Sept. 8th the cornea was clearer above and the hypopyon was less. On Oct. 12th the cornea was only a little clearer, the hypopyon had disappeared, and there was only slight circumcorneal injection. On the 14th she was discharged with vision in the left eye *nil*. A girl, aged 11, was admitted on Oct. 23rd, 1912. On the 19th while playing with the core of a golf ball it ruptured and the contents spurted into her right eye. The upper lid was bound down to the cornea by cicatricial tissue and there were much pain and photophobia. The lid was peeled from the cornea and Cargile membrane was applied to the conjunctival surface. In June, 1913, the cornea was fairly clear towards the periphery, but there was a marked central haze. Vision was 20/200. A boy, aged 13 years, was admitted on April 11th, 1913. Three days before he opened the core of a golf ball with his pocket knife and the fluid squirted into his right eye. The whole eye looked as if covered with a diphtheritic membrane, and neither the cornea nor the iris could be made out. There were considerable photophobia and swelling of the conjunctiva and lids. After 12 days the membrane had disappeared, leaving the outer third of the cornea clear. Hypopyon appeared about the sixteenth day, and the Saemisch operation was done. On May 29th, when he left the hospital, he could see only shadows. On Oct. 4th the outer and upper fourth of the cornea was clear; the rest was densely leucomatous. There was a large symblepharon from the lower corneal margin to the lower fornix. The United States Golf Association has issued a warning against the dangerous practice of cutting open golf balls, and a Bill has been introduced into the legislature of the State of Massachusetts to prohibit the sale of golf balls containing any caustic fluid.

ACTINOMYCOSIS AND PUBLIC HEALTH.

AN entirely new phase in the history of actinomycosis is now being entered upon as the result of the investigations and conclusions of the medical officers of health of the City and Port of London.[1] These officers find that there is a very considerable traffic in ox tongues from the Argentine Republic, and that a somewhat large proportion of these, about 5 per cent., are affected with actinomycosis either in the blades or in the attached glands. They conclude, therefore, that until action is taken in the Argentine which will ensure that these tongues are carefully examined and the affected ones withdrawn, steps must be taken in the interests of the public health to inspect and regulate this traffic. Though the granules so characteristic of actinomycotic pus were known to Langenbeck and Lebert, and were carefully described by Robin in 1871 as occurring in certain "abscès anciens," it was not until the investigations of Rivolta, Perroncito, and Bollinger during the years 1868–77 on the disease as met with in cattle, that it was recognised as of parasitic nature, and several more years elapsed before the identity of the disease as met with in men and cattle was postulated by Israel and Ponfick. This identity is, however, not admitted by all observers, and there are still lacunæ in our knowledge which, as is suggested in the report we are considering, require to be filled by further investigations. There are certainly a number of varieties of streptothrix found in diseases clinically resembling actinomycosis, some of which are aerobes and some anaerobes, but whether all cases of true actinomycosis in man are caused by the anaerobic form, or whether this holds for the majority of cases in certain localities only, and whether the forms of streptothrix found on fodder grasses are identical with those producing the disease in man and cattle—a convenient and natural assumption—these still remain subjects for investigation. Harbitz and Gröndahl[2] regard the aerobic forms cultivated from plants as differing from the forms found in human disease, and they could not infect experimental animals with these forms. It is certain that human actinomycosis is not the rare disease which at one time it was thought to be, and is met with fairly often in hospital practice, though, owing to the lack of characteristic symptoms, the cases usually masquerade under many diagnoses before their true nature is settled by bacteriological examination. The grounds on which the imported tongues are to be condemned is that they are diseased; the report is careful to state that there is no proof that there is danger of infection, or any evidence that the disease spreads from cattle to man, or even among cattle themselves. There was also no proof or suggestion that the organisms found in the tongues were living. The occurrence of the disease, usually in relation to the gastro-intestinal tract, would naturally cause suspicion to attach to food as a means of infection. Attention is drawn to the difficulty of distinguishing in some cases between the lesions of actinomycosis and tubercle; the search for tubercle bacilli in these cases gave no positive results. The relation of actinomycosis to tuberculosis is, of course, intimate and of great interest, and has been insisted upon and elaborated by Mr. A. G. R. Foulerton in his recent Milroy lectures before the Royal College of Physicians of London.[3] It is partly on account of this connexion, but chiefly because a large percentage of the tongues are affected in the glands alone, that the report suggests a regulation rendering tongues without roots and glands liable to re-exportation. This question of actinomycosis in cattle is obviously entering upon a very interesting and important phase.

THE OCCURRENCE OF UNILATERAL VISUAL HALLUCINATIONS AND MACROPSIA IN A CASE OF CEREBRAL TUMOUR.

Dr. Arnold Josefson, of Stockholm, has published in a recent number of the *Deutsche Zeitschrift für Nervenheilkunde* an interesting case of intracranial tumour in which unilateral visual hallucinations and macropsia formed the chief and localising symptoms. The patient was a woman who began gradually to suffer from intense headaches, situated in the occipital region. Some months later the acuity of her vision commenced to diminish, and not long thereafter giddiness and sickness developed. Her memory for recent events began to fail, and then definite visual hallucinations made their appearance. The patient said they took the form of stars, brown leaves, rings, &c., and that they were always localised in the right visual field. Many of these hallucinatory objects were noted by her to be very much larger than real objects of the same nature would have appeared. On examination it was found that there were double optic neuritis and right homonymous hemianopia. In addition, there was a slight degree of mind-blindness, and possibly also of alexia. It was also noted that the patient's ideas of distance and perspective were very much at fault. During the examination she frequently remarked: "The room seems so big," "The doctor seems so tall and his face so large." Not long thereafter the patient died, and at the necropsy a tumour was discovered in the occipital lobe of the left side, its posterior limit about one and a half centimetres from the occipital pole, extending forwards in the substance of the lobe to the lateral ventricle, into the wall of which it bulged. The anterior part of the lower margin of the calcarine fissure was invaded by tumour growth; the lingual gyrus was also invaded. Microscopically the tumour was a glioma. Among the interesting features of this case is the occurrence of macropsia. It is, of course, well known that macropsia and its opposite, micropsia, are found with certain peripheral lesions of the visual system. Paralysis of accommodation may produce the latter, accommodation spasm the former. The phenomena are by no means rare, further, as an aura in epilepsy, and in such cases, no doubt, the condition is of central origin. It has been remarked in hysteria, and there also the cause must be some central disturbance. Not a few organic cases have been recorded, either of micropsia or macropsia, where the lesion was certainly in the visual or visuo-psychic area of the cerebral cortex (Henschen, Uhthoff, Oppenheim, and others), and this case adds one more to the list. The exact localisation of the phenomenon, however, is by no means determined. Whether it is associated with the degree of mind-blindness from which the patient suffered is not proved. It is known that in that condition disturbances of stereoscopic vision may occur; in Oppenheim's case, however, micropsia was noted in the absence of any form of mind-blindness.

AN EARLY SYMPOSIUM ON VACCINATION.

It is perfectly natural that in the opening years of the nineteenth century, when vaccination was still on its trial, there should have been numerous searchings of heart among old-fashioned medical men as to the efficacy of the new method. Vaccination at first, through being imperfectly understood by the operator, occasionally failed of its object, and we find a certain Dr. John Birch, of Spring Gardens, writing to the Royal College of Surgeons of England in 1807 to say that he believed the practice was decreasing in London, and citing at the same time a number of cases of so-called failure—i.e., the case of Rebecca Latchfield and those of Mr. Watts's children and the inmates of Lambeth Workhouse. But what really strikes the student of old reports on vaccination is the overwhelming unanimity of their writers in favour of Jenner's discovery. In 1806 a number of questions on vaccination were submitted to practitioners throughout the country, and were answered, tersely in most cases, but almost always in favour of what was still regarded as an experiment. The replies of Benjamin Brodie and John Abernethy are notable. The former, at that time assistant to Sir Everard Home, answers very briefly to the effect that he has vaccinated about 100 persons and has heard of no case of small-pox being caught by any of them subsequently. He knows of no case of ill-effects following vaccination. He says emphatically, "None whatever." His letter is dated from Home's house in Sackville-street (Dec. 28th, 1806). Abernethy, whose pupil Brodie had been, writes, using capitals in the eighteenth century manner. His replies are characteristic of the man.

1. How many Persons have you vaccinated? Abernethy: "I believe more than 200."

2. Have any of your Patients had the Small Pox after Vaccination?—in the Case of every such Occurrence, at what Period was the Vaccine Matter taken from the Vesicle?—how was it preserved? How long before it was inserted?—what was the Appearance of the Inflammation?—and what the Interval between Vaccination and the Variolous Eruption? Abernethy answers as follows: "Almost the whole of my Inoculations was done by way of ascertaining the Truth of Doctor Jenner's Assertions and Opinions and shortly after his first publication. I could not believe that the Action of so mild a poison as the vaccine could exempt the Constitution from the Influence of so potent a Contagion as the Small Pox; but though I tried by repeated inoculations and by exposing patients in Air which actually stank with variolous effluvia, I could never communicate that disease to persons previously vaccinated. It was upon the Ground of these Experiments, that I subscribed my name to a paper recommending vaccine inoculation to the public. Since that Time my Experience has been very limited as I have only inoculated the children of a few of my friends. I have not heard of any failure in these or former cases."

In answer to the question, "Have any bad effects occurred, in your Experience, in Consequence of Vaccination?—and, if so, what were they?" Abernethy merely answers, "None." "I do not know," he replies in answer to the fourth and last question, which is to this effect—"Is the Practice of Vaccination increasing, or decreasing, in your neighbourhood?—if decreasing, to what Cause do you impute it?" The document is signed "John Abernethy, Bedford Row, 31st Decr., 1806."

A TETANIC FORM OF URÆMIA.

Very few cases have been published of a form of uræmia simulating tetanus, and these leave much to be desired. They belong to a period anterior to the use of modern methods of examination, such as lumbar puncture and estimation of the amount of urea in the blood and cerebro-spinal fluid. The rarity and unsatisfactory nature of the records have led Professor Chauffard to doubt the existence of this form of uræmia. Hence the importance of the following case reported at a meeting of the Société Médicale des Hôpitaux of Paris on Nov. 14th, 1913, by M. A. Bergé and M. Pernet. A single woman, aged 61 years, was taken to the Broussais Hospital on Sept. 10th, 1912, in a state of "generalised contracture" which had followed a fall. She was first admitted as a surgical case, but as the surgeon could find no wound and the accident appeared to have been trivial she was transferred to the medical side with the diagnosis of tetanus. The history was that she had been in good health until ten days previously, when she fell on the stairs. Eight days later she was attacked with trismus, slight dysphagia, and stiffness of the neck. On admission she was perfectly conscious, and was positive that she never previously suffered from any disease. On examination there was generalised rigidity, the head was retracted and buried in the pillow, the jaws were clenched, and the abdominal muscles were tense, giving to the abdomen a wooden feeling. The lower limbs were contractured in extension; the adductors stood out like tense cords. The upper limbs were slightly contractured in flexion. At intervals attacks of slight opisthotonos occurred. On attempting to flex the head the whole body was raised from the bed. There was no risus sardonicus. The eyes were kept constantly shut, but could be easily opened. The patient suffered no pain. The pupils were not contracted and reacted normally. The pulse ranged from 100 to 120, and the temperature from 98·6° to 100·4°F. There was incontinence of urine. The physician in charge of the case, in the absence of M. Bergé, diagnosed tetanus, and gave several injections of antitetanic serum, but the symptoms persisted. On Sept. 16th M. Bergé saw the patient for the first time and agreed with the diagnosis. She was then a little somnolent. On the 17th she became comatose and there was a remarkable change in the condition of the muscles. The lower limbs could easily be flexed and the abdomen was relatively supple, but there was slight rigidity of the upper limbs and the neck was still very rigid. The trismus had disappeared. The eyes were sunken and the conjunctivæ were almost insensitive. The pupils were not contracted and did not react to light. There was Cheyne-Stokes respiration with long pauses during which the patient appeared to be dead. The knee-jerks were normal and Babinski's sign was not present. The pulse was 100 and the temperature 101·3°. This great change in the patient's condition—the coma, Cheyne-Stokes respiration, and attenuation of the contractures—raised a doubt as to the diagnosis of tetanus and suggested uræmia. Urine obtained by the catheter contained a large quantity of albumin and no sugar. Lumbar puncture yielded a clear fluid which was not under increased pressure and did not contain excess of albumin or leucocytes. It contained 3 grammes per litre of urea. Death occurred in the evening. At the necropsy no cerebral lesion was found. There was œdematous congestion of the lungs. The heart weighed 270 grammes and there was no notable hypertrophy of the left ventricle. The kidneys were small and atrophic and their capsules were adherent. The left weighed 95 and the right 98 grammes. The surface was granular. On microscopic examination they showed advanced atrophic sclerotic nephritis. The medulla of the patient was emulsified and injected into guinea-pigs, which did not react in any way. In this case the simulation of tetanus was complete; only the absence of pyrexia could have raised any doubts as to the diagnosis. The only alternative to attributing the symptoms to uræmia is to suppose that tetanus coexisted with the nephritis, but this is excluded by the apyrexia and the negative result of the injection of the guinea-pigs.

THE FOURTH CONGRESS OF THE INTERNATIONAL SOCIETY OF SURGERY.

THE Fourth International Congress of Surgery, which will be held in New York from April 13th to 16th, will miss the stimulating presence of Dr. Lucas-Championnière, who presided at the Third Congress held in Brussels in 1911. Doubtless, however, Professor Depage, of Brussels, to whose energetic work as secretary the undoubted success of the last Congress was largely due, will adequately replace that distinguished surgeon whose loss the surgical world has so recently had to mourn. It is arranged that the steamer *Imperator* shall leave Hamburg on April 2nd, calling at Southampton and Cherbourg *en route* for New York, while the *Rotterdam* will leave Rotterdam on April 4th, calling at Boulogne. The steamers are timed to arrive in New York on April 9th and 12th respectively. The Congress will be opened on April 13th at 11.30 A.M. in the Hotel Astor by the President of the United States. The scientific proceedings will begin at 2.30 that afternoon with the discussion on the Surgery of Gastric and Duodenal Ulcer. On the 14th the reports on Grafting and Transplantation, and on the 15th those on Amputations will be read and discussed. During the Congress operative demonstrations will be given in the different hospitals. Only members of the society, which now numbers some 600 of the world's leading surgeons, can take part in the discussions, but the meetings are open to non-members, and it has been decided that foreign surgeons who are not members shall be permitted, on the recommendation of the delegates of their respective countries, to share in the special arrangements made for the journey. In commenting on the last Congress in THE LANCET of Oct. 21st, 1911, p. 1148, regret was expressed that there was not a much larger attendance in the British section, only 24 being present. We hope that British surgery will be more adequately represented this year. Among the entertainments provided are a special (invitation) luncheon, tea, and dinner on the opening day, a luncheon given by Mrs. Mayo for the ladies and a soirée on the 14th, a subscription banquet on the 15th, and from the 16th to the 28th excursions to Philadelphia, Baltimore, Washington, Chicago, Rochester, Buffalo, Niagara Falls, and Boston. The probable date of departure for Europe is April 28th. Further particulars can be obtained by those interested on application to the Secrétariat Général, 78, rue de la Loi, Brussels.

PSYCHIC EPILEPSY OCCURRING WITHOUT OTHER EPILEPTIC PHENOMENA.

IN the *Journal of Nervous and Mental Disease* for September, 1913, Dr. George E. Price, of Philadelphia, describes the case of a man, aged 42, in whose family history nothing of significance had occurred beyond the insanity of a maternal grandfather, whose symptoms came on after a period of very hard mental and physical work. He was heard by his wife one evening to be snapping an empty revolver in an adjoining room, and when she entered it she found him confused and under the delusion there was a man in the room whom he was trying to shoot. In less than an hour the symptoms disappeared, to be followed, however, by severe headache and sleepiness. During the next month some seven similar attacks occurred, some lasting not much longer than 15 minutes, in all of which the patient was confused and suffered from a vague delusion that there was a strange man in the room. The attacks were always followed by headache, and he had no subsequent recollection of them. As the attacks were becoming more frequent the patient was removed to the Jefferson Hospital and subjected to a full course of bromides. Great improvement resulted, and the "fits" entirely disappeared. In all of them which were observed in hospital it was remarked that the patient's face was suffused. The essential features of the attacks were clouding of consciousness, disorientation, delusions, absolute amnesia, a certain amount of sameness and automatism in the phenomena, and the subsequent severe headache and somnolence. From a consideration of the facts Dr. Price regards the symptoms as those of a true psychical equivalent of epilepsy, although there is no history of convulsive seizures in the patient or in his family. If the mental disorder occurs as the sole manifestation of epilepsy, obviously the diagnosis may be attended with some difficulty. In the present instance, however, there seems no good reason to doubt the accuracy of Dr. Price's view of the case, which is of some medico-legal importance, even though the patient did not actually come in contact with the law. A number of instances of pure psychic epilepsy have already been recorded in the literature.

TREATMENT OF ANKYLOSTOMIASIS.

ANKYLOSTOMIASIS causes the world enormous economic loss. Not so immediately and obviously fatal as plague or sleeping sickness, it yet accounts for much of the unsatisfactory work which is proverbially all that is achieved by many natives in the tropics, and beyond. It attacks myriads of bare-footed labourers in the Southern States of the Union, in Brazil, West and East Africa, India, the Straits Settlements, and in the islands of the South Seas. We recently mentioned that of 127 bodies serially examined post mortem in German West Africa 114 (93 per cent.) showed ankylostoma infection. Besides, as we know, the disease occurs in Europe, even in England. Not only is the working efficiency of its victims greatly reduced, extinguished even, but many of them require prolonged hospital treatment. Thus Dr. R. D. Keith recently[1] described in our columns cases which had to be kept in hospital for six months continuously. It is very important that for a disease so frequent the best and most speedy treatment should be known, and we therefore welcome a paper by Staff-Surgeon Dr. Greisert,[2] which summarises the reports of the surgeons in German East Africa, who had each at the request of the Government treated some hundred cases by four different drugs—beta naphthol, thymol, eucalyptus oil, and male shield fern. Dr. Greisert concludes that this last is far too expensive and unreliable for use in the tropics, and besides has no conspicuous superiority over the others. Eucalyptus oil similarly fails to commend itself, and of the other two, thymol is expensive, unpleasant to take, may cause serious or even fatal accidents, and produces no better results than does beta naphthol. Consequently he recommends this latter, and advises the following simple procedure. A purge may be ordered the night before, then 45 grains (3 grammes) of beta naphthol are given on each of three successive mornings, and it is better that the drug should be fresh. It is not unpleasant to take, patients not seriously ill need not be taken off duty, the period under treatment is short, there are no complicated rules for administration, and no troublesome sequelæ; so that the treatment can be taken in charge by laymen—for example, by planters, and the cost of the treatment, very important when coolies have to be dealt with by the hundred, is small, about 6*d.* It does not, like thymol, kill the other intestinal parasites, but santonin or other vermifuge may be administered simultaneously.

THE SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

THE Society of Tropical Medicine and Hygiene has now taken a room from the Medical Society of London at 11, Chandos-street, Cavendish-square, London, W., for its permanent quarters. Fellows will now therefore be able to use this room from 10 A.M. to 5 P.M. daily, both for reading and for the examination of microscopical specimens. A certain number of exchange publications lie upon the table, and the late Dr. Carnegie Brown's bequest of books forms the nucleus of a small library. These works can also be consulted. It is hoped that Fellows upon arriving home from abroad will make use of the room and also record their home addresses there. By so doing men from different colonies will be able to come into touch with each other, and so exchange ideas. Up to the present time the lack of such accommodation has been felt by many, and the Society hopes, now it has been able to get permanent quarters, that this want will be suitably met.

WE are informed that Mr. A. H. Tubby has been elected a corresponding member of the Société Française de Chirurgie.

HEALTH WEEK COMMITTEE.—The Lord Mayor of London has consented to act as chairman of the General Committee for promoting the Health Week, which will be held from Nov. 15th to 21st, 1914, under the auspices of the Royal Sanitary Institute.

MEDICINE AND THE LAW.

A Medical Man and his Servants: A Question under the National Insurance Act.

AT Stafford Dr. F. M. Blumer was summoned recently for failing to pay a contribution under Part I. of the National Insurance Act in respect of T. Albert, his chauffeur. Dr. Blumer, who defended himself, contended that he was willing to undertake the medical attendance that his servant might require, and that Albert had applied to the Insurance Committee for permission to make his own arrangements. This had not been refused, but had been made conditional upon the defendant's acceptance of the obligations imposed by Form 43. He had refused to bind himself to comply with Form 43; the matter had been referred to the Insurance Commissioners who declined to intervene, and he contended that it was *ultra vires* of the Commissioners to compel him to give the undertaking required by Form 43, or to make his doing so a condition for allowing his servant to make his own arrangements for medical treatment. In consequence of the refusal of Albert's application in the circumstances indicated, and as a protest against the conditions sought to be imposed, the defendant had ceased to pay contributions under the Act in respect of Albert, although paying them in respect of other servants, and although recognising fully that they would have to be paid eventually. He had, in fact, deducted the man's contributions from his wages while not stamping his card, a course which the prosecuting solicitor referred to as a dangerous one, involving the possibility of a further charge. The defence therefore resolved itself into the question whether the conditions imposed by Form 43 were *ultra vires*, and in particular those relating to the keeping of records, to which Dr. Blumer objected as impossible to comply with. The clerk to the Insurance Committee expressed the opinion that the form was provided as a draft agreement only, which need not be adopted in every detail, but that the clause relating to keeping records must be adopted if the full grant from the Commissioners was to be obtained, and further, that whether the form was *ultra vires* or not, the obligation to pay contributions under the Act was not affected. The magistrates appear to have adopted this view, as they stated at the close of the hearing that they had decided by a majority to convict. They considered that Dr. Blumer had believed that he had a good defence, and so imposed a nominal penalty of 1*s.* with costs, and ordered the payment of all arrears. Dr. Blumer intimated that he would comply with this decision, and that the case would go no further. In comment it may be submitted that, whether the point in question was a good one and was properly raised by the refusal to pay contributions or not, the Insurance Commissioners should give their consideration to the following. As administrators of the National Insurance Act responsible for the provision under it of the best available medical attendance for the insured, they have had recently under their own regulations (1) the above case, in which a medical man willing to attend his own servant, who desires to make his own arrangements, has been so hampered with what he regards as impracticable and harassing conditions that he has declined to be bound by them; and (2) the case referred to recently at

Worcester[1] in which persons, also desiring to make their own arrangements for "medical treatment," have been freely permitted to do so with an unqualified person described as a "herbalist."

Eugenics and Cheap Certificates in the United States.

In the State of Wisconsin a law framed to promote eugenic marriages has had the effect of putting an end temporarily to weddings of all kinds. It prescribes a medical certificate based upon the Wassermann test as a necessary preliminary to every union, and fixes the fee at which the medical man consulted is to supply the required document at what would amount to 12*s.* in our coinage. Those acquainted with the purchasing power of money in the United States will estimate the value of such a fee, and the medical profession has refused in a body to accept it. The aid of the law courts is being invoked owing to the attitude of the medical men, and it is pointed out that not only would the application of the Wassermann test be part of the consideration for the payment of 12*s.*, but that in the whole of Wisconsin not more than 25 practitioners would be found capable of applying it.

Medical Witnesses and the Obligation to be Present.

In a recent case at the Old Bailey two medical witnesses had their expenses disallowed on account of their having been absent when their presence in the witness-box was required. In both instances they had been under the impression from a notice in the newspaper that the case in which they were to give evidence was not going to be heard at the time named in the notice, but was only to be made the subject of an application to the court. The police, however, had warned them that they ought to be ready to be called. One of them, Dr. F. S. Toogood, medical superintendent of Lewisham Infirmary, had also been summoned to give evidence in a county court, and had gone there, but Mr. Justice Bailhache intimated that the Central Criminal Court was the superior court, and that if either had to be neglected it should have been the county court. Medical men will note the importance of not disregarding any obligation imposed upon them as witnesses, even though it entails the greatest inconvenience to them, as admittedly it may do. At the same time, in these modern days of telephones and motor-cars, it should be strenuously urged upon the authorities that it is not necessary to keep witnesses of any kind hanging about to their inconvenience and pecuniary loss, if they are willing to fall in with arrangements for summoning them as soon as it is reasonable to insist upon their presence.

The Children Act, 1908, and a Parent's Refusal to have Adenoids Treated in a Child.

In the case described under the above heading in THE LANCET of Nov. 22nd, 1913, p. 1490, the Divisional Court held that the justices were wrong in dismissing a charge under the Children Act, 1908, made against Ishmael Jackson, a dealer, at Melton Mowbray police court. On the case coming again before the bench for reconsideration under the above judgment a penalty of £2 was imposed.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society will be held on Jan. 29th, at 8.15 P.M., at St. Mary's Hospital, W., when a large number of clinical cases will be shown. There will also be demonstrations on actinomycosis, carcinoma of œsophagus and radium therapy, and the use of artificial pneumothorax in phthisis.

LEAD CONTAMINATION OF A WATER-SUPPLY.

ONCE again a peaty moorland supply of water in Yorkshire has proved to be a source of lead poisoning through its action on the lead service pipes. In August, 1913, Dr. W. W. Stainthorpe, medical officer of health for the combined sanitary districts of Guisborough union, reported to the Local Government Board that a number of persons in that district were suffering from illness the symptoms of which suggested lead poisoning. It was further suspected that this illness was due to the presence of lead in the water supplied to the town. The matter has since received the attention of the Local Government Board, which instructed Dr. Frank R. Seymour to visit the district. His report has now been published, from which it appears that before 1912 the possibility of some action of the water on lead was recognised, since the company supplying it adopted a treatment with a view of preventing such action. Analyses had shown that the water as supplied to the consumers either contained lead or was capable of acting upon that metal. Sand filtration was originally adopted for removing organic impurities, but no precaution was taken in regard to negativing the action of the water upon lead until treatment with lime was begun in 1911. Apparently the lime treatment was not established on a uniform basis, for sometimes the public supply proved to exhibit an acid reaction. In other words, both the water and the treatment were subject to independent variations, and it is therefore probable, as Dr. Seymour writes, that "water having in a relative sense a considerable power of acting on lead may have been admitted to the town mains." At all events six samples of the treated water taken under these conditions had no solvent action on lead, although three of them had relatively considerable "erosive" actions. It is a remarkable fact that more cases of lead poisoning were discovered in the town since lime treatment was commenced than had occurred during the years preceding the treatment. Dr. Seymour says that it is difficult to account for this merely by the supposition that acid water was sometimes admitted to the town mains in spite of the treatment, and he suggests that some circumstances hitherto unconsidered must have been at work which tended to increase the plumbo-solvent power of the water. From this inquiry it would seem that treatment with lime, if consistently carried out, will effectively remove the acidity of water to which it owes its plumbo-solvent power, but it is unfortunately possible that as a result of treatment the destruction of plumbo-solvency may be more than counterbalanced by increased ability to "erode" lead. Dr. Seymour suggests that the water company at Guisborough should in future employ a competent analyst for a period sufficient to enable him to devise and carry out a series of differential experiments. These, he considers, should be made in reference both to plumbo-solvency and to plumbo erosive ability and extend over some considerable time, so that the nature of the water at different seasons of the year in storm and in drought may be fully investigated. There is a suggestion also to supplement the lime treatment with carbonate of soda. We may point out that this would in effect amount to adding caustic alkali, since carbonate of soda added to lime would produce caustic soda and carbonate of lime. We think the addition of sulphate of lime would be an interesting experiment in this case, since this salt is slightly soluble in water, and in reacting on lead would produce insoluble sulphate. It may be added that sulphate of lime is a common constituent of most water-supplies which have no solvent action on lead.

MEDICAL AND SANITARY ADMINISTRATION IN THE GERMAN COLONIES DURING 1910-11.

THE annual reports issued by the Imperial Colonial Office at Berlin respecting the medical service of the German colonies are always full of instructive and interesting information.[2] The amount of details given in these reports increases year by year, and the report now before us runs to no fewer than 808 pages. The following are the colonies dealt with in it—viz., German East Africa, the Cameroons, Togoland, German South-West Africa, New Guinea, the Caroline, Marshall, and Palau Islands, and Samoa. These seven colonies have a combined population of about 15 millions, of which upwards of 7¾ millions are included in German East Africa, which is therefore the principal colony belonging to Germany. As considerations of space will not permit us to refer to the medical and sanitary details of each colony we will confine our observations to German East Africa, the report on which occupies about 400 pages of the present volume; it well illustrates the thorough manner in which the treatment and prevention of disease are carried out in Africa by our German cousins.

German East Africa.

The medical and sanitary staff employed in this colony, which comprises an area of 384,079 square miles, includes official and non-official members. To the first of these classes belong the medical officers of the native colonial troops and the German military surgeons serving in East Africa; also the Government civilian medical officers stationed in various districts. With these are associated a number of German and native assistants, trained nurses, Sisters of Mercy, and members of the Red Cross Society. As regards the non-official doctors, a number of business firms have their own medical men to attend their employees, and two railways in course of construction, the Central Railway and the line from Usambara to Tanga, have each a medical staff. There are also some German and English medical missionaries working in the colony who give their services to the native sick gratuitously. Among the Europeans resident in the colony, numbering some 4227, there were 1387 cases of illness treated by the official medical officers, and 43,754 cases among the natives. The chief maladies for which medical advice was sought included malaria and blackwater fever, ankylostomiasis, dysentery (both amœbic and bacillary forms), venereal diseases, frambœsia, and sleeping sickness.

Plague.—Though plague is endemic in that part of the colony lying near Lake Victoria Nyanza there was no widespread epidemic during 1910-11. There were, however, some localised outbreaks, including one at Muanza, to which place, it is alleged, the infection was brought from English territory—namely, Uganda. There was also an outbreak at Lindi, where, as also at Muanza, there was a coincident epizoötic of plague among rats. Great efforts were made to destroy these rodents, and altogether 154,639 were killed up to the end of the fiscal year.

Small-pox.—Though only 560 cases, with 163 deaths, came under official notice, there were numerous other cases in various parts of the colony during the year. The precise number of attacks and deaths of these unofficially attended small-pox cases is not known. Several localised outbreaks occurred, but these were quickly suppressed by the extensive use of vaccination and revaccination. During the year 886,750 vaccinations and revaccinations were performed. The bulk of the vaccine lymph was prepared locally, 320 bovine animals being used for its production. Experiments were also carried out to test the value of lymph obtained from other animals, such as sheep, goats, swine, and rabbits; a donkey and a dog were likewise treated for this purpose. The virulence of the vaccine lymph appeared to be increased by passage through the pig and the donkey.

Ankylostomiasis.—Among the natives the official doctors treated 3816 cases of hookworm disease, 227 of them proving fatal, but only 1 case was reported among the European population. The disease was rife, too, among the native labourers employed in the construction of the Usambara railway, who were not treated by the Government medical officers but by the contractor's surgeons. Of 6203 persons whose stools were specially examined, 2572, or 41 per cent., were found to be infected. The colonial troops also had many cases. For instance, out of a company of Askaris at Lindi numbering 167, upon examination 109 were found to be passing the eggs of the parasite in their stools; and at Daressalem (the capital and chief port of the colony) among the Askari recruits at the depôt numbering 461 there were 98, or 21·8 per cent., infected by the disease. The habits of the natives assist in the spread of the infection, and efforts are being made to induce them to use latrines, but at the plantations some difficulty is experienced in getting members of different tribes to make use of the same latrine. Privy accommodation is also being provided for native huts where possible.

Malaria and blackwater fever.—In the European population 1048 cases of malaria were treated by the Government medical officers, 3121 among the natives and 95 among the military, making a total of 4807 malaria cases officially treated. Of that number 20 died. There were 56 cases of blackwater fever among the European civil population and 26 among the natives, a total of 82, of which 12 proved fatal. Special measures were taken to find out all persons carrying the malarial parasites in their blood, and these underwent careful treatment with quinine; along with this efforts were made to destroy all the mosquitoes' breeding places. At Daressalem the blood of 21,476 people was examined, and 4441 were discovered to have the parasites in their circulation. In 77 per cent. of these cases tropical ring parasites were found. At Tanga, a port on the coast and the terminus of the Usambara railway now in process of construction, 9662 native labourers were examined and parasites were found in 3075 of them. Mention is made of two Englishmen who came under official treatment, having been discovered very ill after some weeks spent in elephant hunting in German East Africa. Neither of these men had supplied themselves with any quinine, although knowingly proceeding to a malarial district. Both of them paid for their neglect with their lives. The meteorological conditions were on the whole favourable, less rain having fallen than in some preceding years.

Sleeping sickness.—Altogether 3573 cases of sleeping sickness came under observation during the 12 months, and 694 of them terminated fatally. According to the scheduled returns given in the report no fewer than 673 are classified as "cured." The cases mainly occurred in two regions—viz., (1) in the region around the Victoria Nyanza, from which 998 cases were reported; and (2) along the shores of Lake Tanganyika, where 2575 cases were notified. The measures employed against the disease are those described in the last report (for 1909-10). Apparently the situation as regards sleeping sickness in the colony is improving. Atoxyl and arsenophenylglycin are the chief remedies used in the treatment of the malady. Trial is also being made of "Hata 606." The expenditure incurred during the 12 months for dealing with this disease amounted to £16,200.

Leprosy.—This malady is widely diffused throughout the colony, and during the year a number of fresh cases came under official observation. On March 31st, 1911, there were 52 leper homes or villages where the patients were segregated and cared for; the number of actual cases of leprosy known at that date was 4335. Some of the leper homes were under the supervision of the medical missionaries.

Relapsing fever.—This infection is endemic in German East Africa, and the disease is commonly observed to spread along the caravan routes and in the stations or resting places of the carriers where the insect host, a tick (ornithodorus moubata), of the specific organism is often to be found. With a view to getting rid of these infections the huts are

[1] Medizinal-Berichte uber die Deutschen Schutzgebiete fur das Jahr 1910-11. Edited by the Imperial Colonial Office. Berlin: E. S. Mittler and Son. 1913. Pp. 808, with 29 illustrations in the text and 20 photographs. Price, unbound, 10 marks.

[2] See also THE LANCET, March 16th, 1912, p. 747.

often burned down. Among natives 391 cases were treated by the Government doctors and 43 among the Europeans; but other cases, the number of which is not stated, were treated by the unofficial practitioners and by the medical missionaries. Of the white officers and non-commissioned officers serving with the colonial troops 17 were attacked by relapsing fever during 1910–11, and among the native soldiers 166 other cases were reported.

Venereal diseases appear to be very prevalent in the colony. Among the European civil population 302 cases and among the natives 2144 were treated by the Government medical men. In addition nearly 400 cases among the coloured population were attended by non-official practitioners. There was an increase among the troops in the number of venereal cases treated by the military surgeons, but this appears to be accounted for by the fact that there is now a much stricter control over the coloured troops, and that in consequence the occurrence of venereal disease is brought under medical treatment much more quickly and surely than in the past.

We have said enough to show the extent and importance of the information contained in this annual report upon the medical and sanitary services of the German colonies.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

City of Liverpool.—Dr. E. W. Hope's report lays especial stress upon the need for classes for children suffering from a degree of myopia rendering ordinary education difficult. A table of the results of an examination of the vision of 7525 children is given showing 356, or 4·73 per cent., with vision 6/24 or worse. The education committee in Liverpool are evidently not awake to the exceedingly serious importance of these figures. Nor, judging by the statement "sewing continues in many instances to be carried on during dark days and sometimes in badly lighted classrooms," are they awake to the importance of safeguarding the children's vision in general. It would be practically a matter of impossibility to have any satisfactory excuse for the condition referred to. It can only be due to ignorance. A short but interesting account is given of the mental condition of children, and it appears that there are constantly waiting for admission to mentally defective classes upwards of 100 children, who in some instances become too old for examination before their turn arrives. Bad nutrition is estimated, using a "lenient" standard, at 10·5 per cent., and in the *Scotland district* nearly 30 per cent. Clothing and boots are very defective in large numbers of cases Under the heading of "treatment" we notice a useful coöperation between the Liverpool Insurance Committee and the Invalid Children's Aid Association, resulting in the extension of "sanatorium benefit" to the dependents of insured persons and the obtaining of the site for a special sanatorium at Leasowe. But there is a great need of open-air recovery schools. *Arrangements are also being made* for the treatment of defects of vision by two salaried medical officers working on two afternoons a week at the treatment centre and other medical men working on a fee basis of 5*s.* per case. Dental treatment and other treatment are urgently required. Two charts dealing with measles, of which there was a severe epidemic during the year, and whooping-cough are given and illustrate the importance of school closure of *infants'* departments. Dr. Hope calls attention to the value, even if measles be accepted as inevitable, of postponing the age at which the disease is contracted and of avoiding a winter epidemic. The value of the charts at the end of the report comparing the defects and other conditions found in the different registration districts would be improved by a clear indication of the differences in density of population, in poverty, and otherwise between these districts.

City of Manchester.—The large scale of the work in this great city has necessitated an increase in the nursing and clerical staff, and calls for increase in premises and in medical staff also. The compulsory notification of measles and whooping-cough has not proved itself of much value except as an indirect means for educating public opinion as to the dangerous nature especially of measles. Ringworm and impetigo are treated by being kept under an "observation clinic," but a means of using X-ray treatment is called for. The amount of the coöperation between the school medical officer and certain voluntary associations has increased, and as a result 76 children suffering from incipient phthisis, anæmia, or debility have been sent to country homes. As many as 348,737 meals were supplied to 5047 children at a cost of slightly over 1*d.* per meal. It would be interesting to know the quantities of food supplied; the meals, judging by the particulars given, cannot be considered adequately to make up for the deficiency in the diet of those needing "free meals." When the family income is over 2*s.* 6*d.* per head in families having over three children, or 3*s.* a head in families of one or two children, a charge of 1*d.* a meal is made. Only 1579 children were fed more than six months of the year. Full reports are given by Dr. A. Brown Ritchie on the special schools and classes as well as the other routine departments of the work, and reports on "Squint in School Children" and "Colour Work in Schools" (dealing with the education of the colour sense), by Dr. E. F. M Neave and Dr. J. G. Woolham, are included.

VITAL STATISTICS.

VITAL STATISTICS FOR 1913.

THE following statement shows the birth- and death-rates and the rates of infantile mortality in England and Wales and in certain parts of the country during the year 1913, the figures being provisional:—

—	Annual rate per 1000 living			Deaths under one year to 1000 births.
	Births.	Deaths.		
		Crude.	Standardised.	
England and Wales	23·9	13·7	13 4	109
96 great towns, including London	25·1	14·3	14·7	116
145 smaller towns	23·9	12·8	13 0	112
England and Wales less the 241 towns	22·2	13·1	12·1	96
London...	24·8	14·2	14 2	104

The standardised death-rates (formerly called corrected death-rates) are the rates which would have been recorded had the sex [illegible] been [illegible] 1901. [illegible] to be

HEALTH OF ENGLISH TOWNS.

[illegible] Welsh towns, with populations [illegible] the last Census and whose [illegible] middle of this year is estimated [illegible] births and 5917 deaths were [illegible]

last week ranged from 5·9 i[illegible] Hornsey, 9 7 in Ilford, and [illegible] Burnley and in Middlesbrough, 23·2 in Exeter, 24·3 in Plymouth and in West Hartlepool, 24·4 in Halifax, and 25·1 in Barnsley.

The 5917 deaths [illegible] number in the pr[illegible] referred to the prin[illegible] 355 in the two [illegible] 80 resulted from [illegible] diphtheria, 66 f[illegible] from measles, 37 from scarlet [illegible], but not one from small-pox. [illegible] from these diseases last wee[illegible] against 1·0 [illegible] weeks. The [illegible]

The deaths [illegible]

and 65 in the three preceding weeks, further rose to 70 last week, and included 14 in London, 11 in Birmingham, 4 in Portsmouth, 4 in Manchester, and 3 in Sheffield. The fatal cases of whooping-cough, which had been 61, 76, and 64 in the three preceding weeks, were 66 last week; 13 deaths occurred in London, 13 in Birmingham, 5 in Sheffield, 4 in Manchester, and 3 in Swansea. The deaths attributed to measles, which had been 80, 76, and 66 in the three preceding weeks, further declined to 55 last week, and included 6 in Bristol, 5 in Barnsley, 4 in Salford, 4 in Burnley, and 3 each in Ipswich, West Bromwich, Bradford, Sheffield, and Middlesbrough. The deaths referred to scarlet fever, which had been 38, 34, and 43 in the three preceding weeks, fell to 37 last week, of which 7 were registered in Sheffield, 4 in London, 4 in Birmingham, and 2 each in Brighton, Manchester, Salford, Leeds, and Middlesbrough The fatal cases of enteric fever, which had been 20, 16, and 28 in the three preceding weeks, fell to 21 last week, and included 5 in London, 2 in Sheffield, and 2 in Rhondda.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily declined from 4143 to 3757 in the six preceding weeks, further fell to 3676 on Saturday last; 388 new cases were admitted during the week, against 326, 425, and 416 in the three preceding weeks. These hospitals also contained on Saturday last 1081 cases of diphtheria, 219 of whooping-cough, 58 of measles, 56 of enteric fever, and 1 of small-pox. The 1469 deaths from all causes in London were 310 fewer than the number in the previous week, and were equal to an annual death-rate of 17·0 per 1000. The deaths referred to diseases of the respiratory system, which had been 280, 423, and 511 in the three preceding weeks, fell to 400 last week, but were 89 in excess of the number recorded in the corresponding week of last year.

Of the 5917 deaths from all causes in the 97 towns, 178 were attributed to various forms of violence, and 438 were the subject of coroners' inquests. The causes of 49, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, Bristol, Bradford, Hull, Nottingham, and in 66 other smaller towns. Of the 49 uncertified causes of death, 9 were registered in Birmingham, 6 in Liverpool, 4 in Gateshead, 3 each in Stoke-on-Trent, Preston, Sunderland, and South Shields, and 2 in Stockport.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1207 births and 896 deaths were registered during the week ended Saturday, Jan. 17th. The annual rate of mortality in these towns, which had been 17·9, 20·3, and 20·2 per 1000 in the three preceding weeks, rose to 20·4 per 1000 in the week under notice, against a rate of 17·0 in the 97 large English towns. Among the several Scotch towns the death-rate last week ranged from 10·1 in Motherwell, 11·0 in Falkirk, and 14·1 in Clydebank, to 22·4 in Paisley, 23·0 in Hamilton, and 31.5 in Ayr.

The 896 deaths from all causes were 7 in excess of the number in the previous week, and included 67 which were referred to the principal epidemic diseases, against 85 and 79 in the two preceding weeks. Of these 67 deaths, 29 resulted from measles, 13 from diphtheria, 9 from whooping-cough, 8 from scarlet fever, and 8 from infantile diarrhœal diseases, but not one from enteric fever or from small-pox. These 67 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·5, against 0·9 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 37, 50, and 36 in the three preceding weeks, declined to 29 last week; of this number 9 occurred in Glasgow, 6 in Edinburgh, 6 in Paisley, and 4 in Greenock. The deaths referred to diphtheria, which had been 10, 12, and 14 in the three preceding weeks, were 13 last week, and included 5 in Glasgow, 5 in Aberdeen, and 2 in Edinburgh. The fatal cases of whooping-cough, which had been 11, 5, and 5 in the three preceding weeks, rose to 9 last week, of which 2 were recorded in Glasgow, 2 in Paisley, and 2 in Coatbridge. The deaths attributed to scarlet fever, which had been 11, 7, and 9 in the three preceding weeks, were 8 last week, and included 4 in Glasgow. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 9, 11, and 12 in the three preceding weeks, fell to 8 last week, of which 2 were registered in Glasgow, 2 in Aberdeen, and 2 in Leith.

The deaths referred to diseases of the respiratory system, which had steadily increased from 139 to 184 in the four preceding weeks, further rose to 230 in the week under notice; 26 deaths were attributed to various forms of violence, against 30 and 33 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 647 births and 500 deaths were registered during the week ended Saturday, Jan. 17th. The annual rate of mortality in these towns, which had been 15·9, 25·7, and 25·4, per 1000 in the three preceding weeks, declined to 21·6 per 1000 in the week under notice. The annual death-rate last week was equal to 24·0 in Dublin (against 17·0 in London and 21·1 in Glasgow), 22·7 in Belfast, 19·7 in Cork, 12·7 in Londonderry, 29·8 in Limerick, and 15·2 in Waterford, while in the 21 smaller towns the mean death-rate did not exceed 16·9 per 1000.

The 500 deaths from all causes were 88 fewer than the number in the previous week, and included 38 which were referred to the principal epidemic diseases, against 32 and 44 in the two preceding weeks. Of these 38 deaths, 12 resulted from scarlet fever, 11 from infantile diarrhœal diseases, 6 from measles, 4 from whooping-cough, 3 from enteric fever, and 2 from diphtheria, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·6 per 1000; in the 97 large English towns the corresponding rate did not exceed 0·9, while in the 16 Scotch towns it reached 1·5 per 1000. The deaths attributed to scarlet fever, which had been 7, 3, and 13 in the three preceding weeks, were 12 last week, of which 10 occurred in Belfast. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 7, 6, and 7 in the three preceding weeks, rose to 11 last week, and included 6 in Dublin and 3 in Belfast. The fatal cases of measles, which had increased from 1 to 8 in the six preceding weeks, fell to 6 last week, of which 4 were recorded in Armagh. The deaths attributed to whooping-cough, which had been 10, 7, and 5 in the three preceding weeks, further fell to 4 last week, of which 2 occurred in Newtownards. The 3 deaths referred to enteric fever were recorded in Dublin and were equal to the average in the three preceding weeks. The 2 fatal cases of diphtheria were registered in Belfast.

The deaths referred to diseases of the respiratory system which had been 89, 162, and 154 in the three preceding weeks, declined to 130 in the week under notice. Of the 500 deaths from all causes, 153, or 31 per cent., occurred in public institutions, and 6 resulted from various forms of violence. The causes of 17, or 3·4 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: M. Cameron to the *Cornwall*; P. H. M. Star to the *Conqueror*; H. P. Jones to the *Columbine*, additional, for Queensferry Sick Quarters; and H. B. Beatty to the *Pembroke*, additional, for East London Recruiting District and for medical charge of Naval Store Depôt. Staff-Surgeons: A. R. Thomas to the *President*, additional, for the *Maine*; and R. S. Osborne to the *Birmingham*, on commissioning. Surgeons: G. A. Finegan to the *Woolwich*; S. F. Dudley to the *Pembroke*, additional, for Chatham Hospital for instruction of Sick Berth Reserve; H. E. Y. White to the *Excellent*, temporary; W. L. Cowardin to the *Jason*, additional, for duty with Mine-sweeping Gunboats; T. Cock to the *Blake*; F. St. B. Wickham to the *Sirius*, for voyage out, on commissioning, and to the *Alert*, on recommissioning; H. White to the *Victory*, additional, for disposal, and for Portsmouth Dockyard; G. Carlisle to the *Victory*, additional, for Haslar Hospital; A. G. V. French to the *Carnarvon*; A. M. Henry to the *Minotaur*; and L. A. Moncrieff to the *Vivid*, additional, for Plymouth Hospital.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Supernumerary Lieutenant-Colonels are restored to the establishment: T. du B. Whaite, vice R. S. F. Henderson (dated Jan. 2nd, 1914); Herbert E. Winter, vice G. A. T. Bray, Supernumerary (dated Jan. 20th, 1914); and Captain Leonard Cotterill to be Major (dated Dec. 5th, 1913).

Surgeon-General W. G. A. Bedford, C.M.G., has taken up duty as Deputy Director of Medical Services to the South African Command, in succession to Surgeon-General O. E. P. Lloyd, V.C., C.B.

Colonel A. E. Tate has taken up duty as Assistant Director of Medical Services at headquarters of the Bangalore Brigade, vice Colonel F. H. Treherne.

Lieutenant-Colonel C. W. R. Healey has been transferred from the London District to the Royal Herbert Hospital at Woolwich. Lieutenant-Colonel C. H. Melville has taken over charge of the Military Hospital at Tidworth, Salisbury Plain. Lieutenant-Colonel J. W. Bullen has been appointed to the Northern Command. Lieutenant-Colonel F. J. Morgan has been appointed to hold medical charge of the transport s.s. *Plassy* leaving Bombay on March 12th.

[illegible] ry [illegible] een [illegible] the [illegible] to [illegible] W. [illegible] uty [illegible] has [illegible] ona [illegible] W. [illegible] ty. [illegible] om [illegible] L. L. G. Thorpe [illegible] Military Hospital [illegible] Madras. Major [illegible] of the depôt of [illegible] ice Major W. K. [illegible] ppointed to the Dublin District for duty. Major G. Baillie has been appointed to the Military Hospital at Colchester. Major G. J. Stoney Archer has been selected for appointment as Specialist in Operative Surgery to the Royal Victoria Military Hospital at Netley. Major H. K. Palmer has been appointed to the Southern Command for duty. Major C. H. Carr has taken up duty at the Military Hospital, Tidworth, on transfer from Upavon. Major J. H. Campbell, D.S.O., has been appointed Medical Inspector of Recruits to the Eastern Command. Major E. S. Clark has embarked for a tour of service in India.

Captain O. C. P. Cooke has been transferred from medical charge at Tipperary to the Military Hospital at Cork. Captain J. L. Wood has taken up duty at Pontefract on transfer from the Military Hospital at Naini Tal Cantonment. Captain C. P. O'Brien Butler, on arrival home from the Military Hospital at Kirkee Cantonment, has been appointed to Kildare for duty. Captain E. M. Pennyfather has embarked for a tour of service in India. Captain S. [illegible] nder orders for transfer from the [illegible] to the Burmah Division for a [illegible] W. Brown has been appointed to the Irish Command on arrival home from Jhansi. Captain C. M. Rigby has been appointed Embarkation Medi[illegible] arriv[illegible] at R[illegible] been [illegible] Poon[illegible] for duty from India, tour expired. Captain M. J. Lochrin has been appointed to [illegible] J. St. A. Maughan has [illegible] the Royal Victoria M[illegible] D. H. C. MacArthur has been transferred from the Military Hospital at Lahore to Dalhousie Cantonment. Captain E. D. Caddell has arrived home on leave of absence from the Military Hospital at Aden. Captain D. Ahern has arrived home for duty from Egypt. Captain A. C. Amy has been appointed to the Eastern Com[illegible] Captains have joined the Royal Army Medical College at Grosvenor-road, S.W., for the courses of instruction for promotion to the rank of Major:—F. D. G. Howell, P. Sampson, E. M. O'Neill, T. W. O. Sexton, T. T. H. Robinson, and G. H. Stevenson. Captain R. G. H. Tate has been appointed to the Irish Command. Capt[illegible] home for duty from Ceylon. [illegible] selected for appointment as [illegible] Sierra Leone Protectorate. [illegible] up duty at Maymyo. Captain R. H. Bridges has taken up duty as Adjutant to the Royal Army Medical Corps School of Instruction at Manchester.

Lieutenant E. C. Lang has been transferred from Kildare to Kilbride. Lieutenant J. C. Sproule has taken up duty at the Military Hospital, Devonport [illegible] Lieutenant F. R. B. Skrimshire, [illegible] Lieutenant E. A. Strachan, and [illegible] have embarked for [illegible] tenant H. C. Todd has been [illegible] Hospital at Bangalore to und[illegible] in Indian sanitation. Lieutenant H. R. L'Estrange has embarked for a tour of duty at Mauritius. Lieutenant T. H. Balfour has been transferred from medical charge at Fort George to Inverness. Lieutenant R. F. Bridges has been transferred from the Military Hospital at Cherat to Peshawar C[illegible] J. D. Bowie has taken up [illegible] nant C. M. Finny has been [illegible] duty at the Military Hospital. Lieutenant F. Hayes has been transferred from the Military Hospital at Poonamallee to Bangalore Cantonment.

INDIAN MEDICAL SERVICE.

Colonel R. W. S. Lyons has taken up duty as Surgeon-General with the Government of Bombay, vice Surgeon-General H. W. Stevenson, C.S.I. The services of Colonel R. Robertson have been placed permanently at the disposal of the Commander-in-Chief in India for appointment as Assistant Director of Medical Services.

Lieutenant-Colonel J. G. Hulbert, civil surgeon at Moradabad, has been granted six months' general leave of absence home from India. Lieutenant-Colonel V. G. Drake-Brockman has been appointed Agency Surgeon (first class) at Bundelkhand.

Major S. R. Christophers has been appointed to act as Director of the Central Research Institute at Kasauli, vice Major W. F. Harvey. Major T. S. B. Williams, agency surgeon (second class), has been appointed to hold civil medical charge at Dera Ismail Khan. The services of Major A. C. MacGilchrist have been [illegible] cial duty under the orders of the [illegible] Medical Service. Major J. K. S. [illegible] on leave of absence from India.

Captain F. W. Cragg has been appointed to officiate as Assistant Director at the Central Research Institute, Kasauli, during the absence on deputation of Captain J. Cunningham. Captain R. B. S. Sewell has joined the Army Department. Captain W. R. J. Scroggie has been granted 2 years and 15 days' general leave of absence home from India. Captain H. Crossle has been appointed an Agency Surge[illegible] the Gover[illegible] ined at Eta[illegible] on leave [illegible] has taken [illegible] the Gover[illegible] ser, civil s[illegible] uli. Captain D. S. A. O'Keefe has been granted 15 months' general leave of absence home from India. Captain W. F. Brayne, plague medical officer in Burma, has been appointed to officiate as Deputy Sanitary Commissioner to the Government of Burma. Captain J. Woods has been granted an extension of leave of absence home from India. Captain R. S. Townsend, plague medical officer at Aligarh, has been appointed to hold civil medical charge at Muttra, vice Captain H. C. Buckley, granted leave of absence.

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd North Midland Field Ambulance, Royal Army Medical Corps: Lieutenant Martin Hallam resigns his commission (dated Jan. 21st, 1914).

1st South Midland Field Ambulance, Royal Army Medical Corps: Lieutenant Edward J. Boome to be Captain (dated August 19th, 1913).

North Midland Clearing Hospital, Royal Army Medical Corps: Lieutenant-Colo[illegible] the 2nd North Midlan[illegible] Medical Corps, to be [illegible] 1914).

West Riding Clearing Hospital, Royal Army Medical Corps: Lieutenant-Colonel Algernon Edward Luke Wear, from the 1st West Riding Field Ambulance, Royal Army Medical Corps, to be Lieutenant-Colonel (dated Jan. 21st, 1914).

Welsh Clearing Hospital, Royal Army Medical *Corps:* Major Conrad Theodore Green, from the List of Officers attached to Units other than Medical Units, to be Lieutenant-Colonel (dated Nov. 12th, 1913).

Attached to Units other than Medical Units.—Captain William A. Gibb to be Major (dated Dec. 3rd, 1913). Lieutenant Alfred S. Bruzaud to be Captain (dated Dec. 4th, 1913).

AEROPLANES AND THE ARMY MEDICAL SERVICE.

The Use of Aeroplanes to the [illegible] art of medical [illegible] carry [illegible] or 20 [illegible] hetist, [illegible] lowed [illegible] being [illegible] r the [illegible] ncipal medical service u[illegible] only yesterday the [illegible] s in practical use and its future suggests many possibilities. In coming wars the aeroplane may play a very important part and already, [illegible] very good work has been [illegible] article published in the [illegible] for July, 1913, by Captain [illegible] article the desirability of

the Royal Army Medical Corps possessing its own aeroplanes was referred to, and it was also pointed out that in France, the birthplace of modern aviation, the medical department had already taken up the new science.

The Medjidieh Decoration.

Captain R. J. C. Thompson, R.A.M.C., has been granted His Majesty's licence to wear the Imperial Ottoman Order of the Medjidieh (Fourth Class) conferred on him by H.H. the Khedive of Egypt.

Colonel Sir W. B. Leishman, R.A.M.C., has been appointed a member of the Army Medical Advisory Board as an expert in tropical diseases.

Home and Foreign Notes.

(From our own Correspondents.)

BIRMINGHAM.

Wolverhampton and Staffordshire General Hospital.

On Jan. 12th the new pathological laboratory of the hospital was opened. The building, which cost £1300, has been erected from plans by Mr. A. W. Worrall, and the equipment will cost an additional £100. It will be in charge of Dr. William Boyd, who was appointed pathologist at the hospital last June. While the laboratory is to be used primarily for the hospital, provision will be made for the needs of general practitioners and of veterinary surgeons. The opening ceremony was performed by Sir Clifford Allbutt. Mr. Shaw-Hellier, the chairman of the board of management, presided, and gave a sketch of the hospital's history. Sir Clifford Allbutt gave an interesting address upon the growth of pathology and the uses of a clinical laboratory.

Birmingham and Midland Institute.

Sir Frederick Treves has been asked to accept the office of president of the institute for the ensuing year. In the long roll of distinguished men who have held this office the last medical president was Professor Huxley in 1871. Mr. Gilbert Barling, in proposing Sir Frederick Treves, remarked that he would be the first surgeon to hold the office, and was not only a distinguished surgeon, and a speaker of great force, but a widely cultured man, who had written some extraordinarily interesting books.

Antivivisection.

The British Union for the Abolition of Vivisection, following the practice adopted elsewhere, have opened a shop in the chief street of the city for the exhibition of the usual misleading models and diagrams. This aroused some newspaper correspondence, and has been followed up by the visit of Dr. W. R. Hadwen, who delivered an address at Queen's College on Experiments on Animals, Useless and Cruel. The speaker's statements did not pass without protest, and there was considerable disorder. The Research Defence Society is opening a shop in the same street as an antidote to the misleading statements about experiments on animals. The local branch of the society has many influential members under the presidency of Mr. Cary Gilson, the headmaster of King Edward VI. Grammar School.

State Insurance.[1]

Of the 320,000 insured persons in Birmingham 263,416 at the end of the year had selected their own medical men, and 446 had been allowed to make their own arrangements. The 260,000 divided among 272 practitioners on the panel would give an average of about 968 per medical man. But one practitioner has 4164 insured persons on his books, 12 have more than 3000, 28 between 2000 and 3000, and 122 between 1000 and 2000. The total remuneration to the medical profession has been as follows: April quarter, £20,374; July, £21,947; October, £23,048; and for the last quarter it will probably exceed £25,000, as many more insured persons have lately chosen their medical men. The average income has therefore, been about £330, but a few have received over £1000. The number of chemists on the pane is 149. In the first nine months the money in hand was just sufficient to meet the cost of the drug service, but since then the average cost o prescriptions has risen, and some anxiety is fel lest the cost should exceed the available balance As far as the first year of practice is concerned there seems little hope of the floating 6*d.* being obtained by the medical profession. Complaint is made in the *Midland Medical Journal* that the extravagant prescribing of a handful of men has cost the profession no less a sum than £7000.

Typhoid Fever.

Cases of typhoid fever have apparently been traced to the eating of Portmadoc mussels, and owing to the action of the health committee dealers have refused to receive further consignments Birmingham is the largest market for these mussels, and the fishermen have petitioned the Portmadoc council to lay down purifying beds.

A serious outbreak of typhoid fever has occurred at Kenilworth, and been traced to contamination of the drinking water. The Local Government Board has made an inquiry, and the inspector's report is expected shortly. Meanwhile a public safety committee has been appointed to watch over the interest of the inhabitants. The cause of the outbreak—an adit polluting the main supply—has been stopped and the mains have been disinfected. Bacteriological examinations now show that the water is pure.

Jan. 20th.

WALES.

Housing in Monmouthshire

It is nearly 20 years since the late Mr. T. W. Thompson, one of the medical inspectors of the Local Government Board, reported upon the grossly insanitary condition of the urban district of Blaenavon in Monmouthshire. In December, 1911, Dr. Morgan J. Rees again reported to the Board on the same district,[1] and stated that he found that Mr. Thompson's observations with respect to the unsatisfactory state of the sewerage and house drainage, sewage disposal, excrement and refuse disposal, and water-supply might very well apply to the then conditions. Of the housing conditions Dr. Rees had a deplorable story to relate. Many of the houses were of a poor character, badly built in the first instance and allowed to become unwholesome and insanitary through lack of periodical repair. Many cases of overcrowding were found to exist, and bedrooms which had been occupied at night were also occupied in the daytime by workmen working on night shifts. Cellar dwellings and back to earth dwellings, though condemned as unfit for habitation, were fully occupied owing to the absence of better houses. Following upon this report the Local

[1] The Lancet, May 18th, 1912, p. 1364.

Government Board has been pressing the district council to make use of the powers invested in it by the Housing, Town Planning, &c., Act, 1909, and to carry out a building scheme. In August, 1912, a definite proposal was made by a member of the district council to erect 50 houses, but the proposal after being deferred from one meeting to another was finally negatived. At one of these meetings it was stated that among 225 houses which had been inspected 40 per cent. had no back doors and 40 per cent. were overcrowded. Failing action being taken by the district council the Local Government Board has now made an order requiring a scheme for the erection of at least 50 houses to be submitted to it by Feb. 26th next, and further requiring that the whole of the houses shall be ready for occupation by Nov. 26th of this year.

The Salary of the Brecknockshire County Medical Officer of Health.

The Brecknockshire county council has recently appointed a medical officer of health and school medical officer at a combined salary of £500 per annum, which sum is to include any expense that the officer may be put to in travelling about the county in the course of his duties. The area of Brecknockshire is 469,281 acres, and there are only three other Welsh counties of greater extent. While the question of the appointment was under the consideration of the county council a communication was received from the Board of Education in which reference was made to the unsatisfactory proposal to pay an inclusive salary out of which the school medical officer would have to pay his travelling expenses. The Board pointed out that in a district like Brecknockshire such an arrangement was open to serious objection, for the greater the efficiency with which the work was done the smaller would be the remuneration of the officer. The desirability for more frequent visitation of the schools in the county made it important that the proposed method of payment should be abandoned, and that the school medical officer should receive a salary commensurate with the responsible and onerous character of the duties to be performed.

The More Adequate Punishment of Defaulting Dairymen.

It has been apparent for many years that the fines that have been inflicted on dairymen convicted of selling milk to which water has been added have been quite insufficient to act as a deterrent to the practice. It has been pointed out more than once by prosecuting solicitors that a dairyman who has even only a moderately sized business can very well afford to pay a fine of £1 or 30*s.* if he sells water at 4*d.* a quart and chooses to run the risk of being found out. It is satisfactory to find that some police magistrates are at last realising that heavier punishment must be inflicted upon dairymen who are convicted of watering milk if the practice is to be stopped. In the Rhondda police court a milk vendor was recently fined £30 and costs for selling milk said to be deficient in butter fat to the extent of 20 per cent., and at the Cardiff police court a farmer who had given a warranty with milk sold by him to a milk vendor was fined £20 and costs for a similar offence.

West Wales Asylum.

The West Wales Asylum at Carmarthen, which serves the counties of Cardigan, Carmarthen, and Pembroke, has accommodation for 600 patients, but for some time the need for enlarging the institution has been apparent, and at the end of 1913 there were in the asylum as many as 724 patients. Difficulty is being experienced at Carmarthen, as at other asylums in the country, in obtaining junior medical officers. A salary of £180 per annum, with four yearly increments of £10, has failed to attract any candidates for a vacant post. The joint committee has therefore decided to offer £200, rising to a maximum of £240 per annum.

Jan. 20th.

SCOTLAND.

The Annual Dinner of the Royal College of Physicians.

THE annual dinner of the Royal College of Physicians of Edinburgh was held on Friday evening, Jan. 16th, at the hall of the College, Queen-street, Edinburgh, Dr. Graham Brown, the President of the College, being in the chair. Some 300 Fellows and their guests were present, the latter including a large number of representative public men in many professions. It was an understood thing that the annual dinner this year would be the occasion of making a more or less public pronouncement with regard to a new and great institute for medical research which has been projected by the Royal College of Physicians, the Royal College of Surgeons, and the University of Edinburgh, with the substantial assistance of the Carnegie Trustees, and the opening speeches were very brief in order to allow time for addresses on the main theme by Sir William Turner, Principal of the University of Edinburgh, and Sir Clifford Allbutt, Regius professor of physic in the University of Cambridge. Dr. Graham Brown proposed in happy terms the toast of "The Imperial Forces," which was replied to by the General Officer Commanding-in-Chief (Scottish Command), who testified eloquently to the advance in the general health of the army during the past 20 years owing to the good work of the medical officers of the services, the spread of knowledge upon sanitary matters, and the spirit of coöperation that had sprung up between the medical department and the other officers of the army. Principal Turner then gave the toast of "Research," and showed step by step how medicine had advanced owing to the achievements of research, and how observation of the finest clinical and scientific sort was as much required now, with the elaborate and perfected assistance offered by our chemical, pathological, and physical laboratories, as ever it had been in the past. He showed how the great new Institute for Medical Research projected immediately for Edinburgh was the natural expression of advancing knowledge, and welcomed the fact that the coöperation of the University of Edinburgh with the Royal Colleges showed a perfect concord of aim between the three bodies, in that all alike were working with the common object of preventing and treating disease. He said that he was permitted to mention that a sum of money would be found by the Royal Colleges and by the University, in which connexion the Carnegie Trustees had been approached, and that the movement, when finally organised, would be associated with the great name of Lister. Professor Clifford Allbutt, in replying to the toast, spoke eloquently of the necessity for medical research to maintain and invigorate the progress of medicine, his address being a comprehensive review of the place that research should occupy in our minds and in the actual course of professional education and life. Professor J. Lorrain Smith having also spoken to the toast, Dr. Alexander Morison proposed the toast of "The Sister Corporations," to which replies were made by the President of the Royal College of Physicians of Ireland, the President of the Royal College of Surgeons of Edinburgh, and the President of the Royal Faculty of Physicians and Surgeons of Glasgow. Dr. C. E. FitzGerald said that he believed his own position as a surgeon-oculist in the Presidency of the Royal College of Physicians of Ireland was unique, but he saw in it a recognition that not only were the diagnoses and observations of ophthalmology every whit as much medical as surgical matters, but that medicine and surgery were one science. Professor J. Ritchie briefly but happily proposed the health of the chairman, Dr. Graham Brown, saying that it was greatly owing to his personality and exertions that in the forthcoming Institute for Medical Research in Edinburgh mutual understanding prevailed between the University and the Royal Colleges, so that "the lion was prepared to lie down with the twin lamb, or, if his hearers preferred it, the lamb was prepared to lie down with the twin lion."

Care of Defective Children in Scotland.

The Scottish Secretary recently received a deputation from a number of Scottish school boards with regard to the fee grant paid in respect of physically defective children. The practice of the Department from 1902 up to March 31st last in calculating the fee grant was to take the same average attendance as for the annual grants; but this method was called to question by the Comptroller and Auditor-General on the ground that it was not legally justified, and the Department has been advised that in future the grant should be calculated on the average actual attendance and not as hitherto, on a basis of 50 for each class. The deputation wished that the *status quo ante* in the method of paying the fee grant should be preserved for the current year, and that thereafter payment might be made by a suitable capitation grant. The chairman of the Govan school board explained that seven of the boards would suffer annually a loss of over £5000 in consequence of the change if no provision were made for payment on a more liberal scale, and that not only would there be keen and universal dissatisfaction, but boards which had not as yet embarked on this type of work would be discouraged from doing so. The Secretary for Scotland, in reply, said that the Scotch Education Department was not to blame in the matter in the least. He was able to say that they had a new arrangement with the Treasury, whereby the grant for defective and epileptic children in special day schools or classes under Article 22–11 (a) of the code should be fixed in future at such a sum as together with the fee grant of 12*s*., and any other additional grant paid under Section 17 (11) of the Education (Scotland) Act, 1908, would amount to £6 per pupil in average attendance. As regarded the similar grant to residential institutions, they agreed that the grant should be fixed at £11, inclusive of fee grant and additional fee grant.

Needs of Argyllshire under the National Insurance Act.

A meeting was held last week in Oban of representatives of the district committee, parish councils, Oban town council, the school board, and the North Argyll Medical Association to consider the information to be supplied to the Highlands and Islands Medical Service Board. Among the suggestions put forward was a proposal for the erection of a central isolation hospital for the district and the subsidising of the Oban Cottage Hospital, so as to enable the managers to admit non-infectious cases where constant attention was necessary, and also maternity cases. A nurse was recommended for Kilbrandan and Kilchattan, Kilninver and Kilmelford, Benduloch and Dalmally, and an additional nurse for Oban. It was further suggested that grants should be made not only for the nurses already established, but also for new nurses, and that a grant of £500 should be made to each local nursing association. It was considered desirable that some sort of scheme should be formulated whereby medical attendance could be provided at a low uniform rate for households where the head of such household does not pay income-tax. It was also suggested that there should be a dentist to visit the various schools in the district, and that a fund be established for consultation in certain cases. It was further proposed that the doctor in each district should have charge of the medical inspection and medical treatment, so far as possible, of the school children in his district. It was recommended that a cycle allowance for nurses be made, and that the Connal Ferry railway bridge ought to be opened for ordinary vehicular traffic to enable patients in Benduloch to be brought within easy distance of the doctors' in Oban and Taynuilt. It was further recommended that each parochial medical officer should have a house provided, and that a fund should be instituted for superannuating parochial medical officers who, on account of age or infirmity, are no longer fit for their duties. Additional doctors were recommended, one in the immediate vicinity of Kilchrenan, and one at Benduloch. It was proposed to put doctors and nurses in direct telephone communication, and it was thought advisable that all hospitals should be in direct communication with the doctors thereof. The telegraph services were also in many cases considered insufficient, and in view of the threatened withdrawal of postal facilities at Bonawe, it was pointed out that such withdrawal would seriously interfere with the medical service at Bonawe and district, where there is a large working population. It was suggested that the telegraph line should be extended from Kilninver to Kilmelford, and that Lochawe should be either cabled or wired to allow telegraphic communication between Kilchrenan and Port Sonachan on the other side of the loch. A motor ambulance for the removal of patients to hospitals and sanatoriums, it was pointed out, would be of great service to all the districts situated on the mainland. Truly the National Insurance Act is far-reaching in its effects!

Working of the National Insurance Act in Aberdeen.

Insured persons in the city of Aberdeen number 54,000, and there are now 65 doctors on the panel. These have been paid the sum of £16,000 for the year. Only 350 insured persons gave notice of their wish to change their panel doctor, and only four doctors requested that patients should be dropped from their lists, the patients thus discarded numbering only five. During the year 250 cases of phthisis have been dealt with in Aberdeen; there has been an average of 40 persons receiving treatment in institutions, the average length of residence being four months. In a number of cases work has been resumed with the disease arrested, but better results are looked for with earlier notification. The Insurance Committee and the Friendly Societies have worked cordially together, and the Act is apparently popular with working men. In the county of Aberdeen there are 40,000 insured persons, the total for Aberdeenshire thus working out at approximately 94,000.

Inverness-shire Sanatorium partly Burned Down.

On the night of Jan. 14th the greater part of the Inverness-shire Sanatorium for Consumptives, near Fort Augustus, an institution working under the National Insurance Act, was destroyed by fire. At the time the fire was discovered, about 7 o'clock, the patients were in the dining-room. The fire spread with great rapidity, and in less than an hour the sleeping quarters, bathrooms, a drawing-room, and part of the dining-room were destroyed. The total loss is estimated at about £1000. The sanatorium was erected some years ago, and accommodated about 24 patients.

IRELAND.

"*Medical Advisers*" *and the Medical Profession.*

SINCE the Irish Insurance Commissioners last summer appointed a number of medical practitioners at fixed salaries to provide certificates for insured persons demanding benefit, the practitioners who accepted such posts have been generally disapproved of by the profession as a whole. This was not merely because it was felt that their acceptance of office presented a solution of the certification question unsatisfactory to the profession, but because their duties entailed the visiting and examination of patients in the care of other medical men. In many cases very strained relations resulted, some of the advisers being so rash as to criticise adversely to the patient the diagnosis and treatment of the medical attendant. It is hoped, as has already been announced in THE LANCET, that the dispute between the medical profession and the Insurance Commissioners concerning certification may soon be amicably settled. The Irish Medical Committee has, therefore, at its last meeting been considering the attitude that should be adopted toward the "medical advisers" both at present and after a settlement is made. The Committee has come to the decisions expressed in the following resolutions:—

> That the Irish Medical Committee, in hope of a speedy settlement of the certification question being arrived at between the Irish Insurance Commissioners and the medical profession, is of opinion that, pending such settlement or failure of the present negotiations, the existing arrangements of the Commission for obtaining evidence of sickness benefit should be acquiesced in by the medical profession, and that pending such settlement or failure of the negotiations no professional interference should be displayed toward the "medical advisers."
>
> That in the event of a settlement of the certification question satisfactory to the Irish Medical Committee being arrived at, the Committee will use its influence to prevent any professional interference being displayed toward the "medical advisers."
>
> That the Insurance Commissioners use their statutory powers and influence to prevent Friendly Societies from penalising any doctors who have remained loyal to the majority of their colleagues.

The Allan A. Ryan Hospital.

Some three years ago the corporation of Dublin leased their isolation hospital on the Pigeon House Hall at a nominal rent to the Women's National Health Association, to be used as a hospital for tuberculosis. It contained some 50 beds, and over a thousand patients have been treated. For the most part the patients treated have been in the secondary stage of pulmonary phthisis. As part of its general tuberculosis scheme the corporation has now resumed possession of the hospital, which is to be kept as a home for advanced cases of tuberculosis. Last Monday at the Mansion House the Countess of Aberdeen handed over to the Lord Mayor formal possession of the institution.

County Down Practitioners and the National Insurance Act.

A meeting of the medical practitioners of North Down held in the Medical Institute, Belfast, on Jan. 12th, decided, as they were requested, to continue on the panel until March 31st, 1914, which is the end of the financial year, the new terms to come into force on that date. A resolution was passed:—

> That we regret that whilst the medical men on the panel for North Down have honourably carried out their contract with the National Insurance Commissioners this year, the Commissioners have failed to fulfil their part of the contract, as they have not yet remunerated any of the medical men for their services in giving certificates to the insured persons.

A motion was also passed urging that insured persons who have not selected a medical man on the panel should be distributed equally among the medical men in the same dispensary district. At a meeting of the members of the County Antrim Local Medical Committee, held in the town hall, Ballymena, it was decided, at the request of the Irish Medical Committee, to renew the agreement with the Insurance Commission until March 31st next.

Derry County Infirmary Salaries.

The committee of the Derry Infirmary advertised for an assistant medical officer, at a salary of £80 per annum, with apartments, and it was announced at a meeting of the committee on Jan. 13th that there were no applicants, the excuse being the demand for junior practitioners in England to work the National Insurance Act. It was then decided to offer a minimum salary of £90, and not exceeding £100, and to appoint a subcommittee to communicate with some of the medical schools with a view to obtain applicants.

The late Mr. J. Gorman, Bangor.

On Jan. 12th, at a meeting held in Bangor, co. Down, it was decided to erect a memorial to the late Mr. J. Gorman, L.R.C.P. & S. Edin., to take the form of an enclosed grave and tombstone in the cemetery and to endow a free bed in the Bangor Hospital, with which Mr. Gorman had been so closely associated since it was built.

Epidemic of Measles in Armagh.

There has been recently a very serious epidemic of measles in Armagh and district, especially among children, and in several cases there have been as many as four deaths in one house. The schools have not yet been reopened.

Jan 20th.

PARIS.

A Leguminous Regimen in Diabetes.

Dr. Marcel Labbé has urged before the Académie de Médecine the claims of a dry vegetable regimen for diabetics, particularly those threatened with acidosis and coma. He considers this an advance on von Noorden's oatmeal cure, which is not borne equally well by all. Dr. Labbé is particularly concerned over the danger of albumin for diabetics, and he entirely forbids meat. He causes each patient to take daily 300 grammes of dry vegetables, 150 grammes of butter, from 3 to 6 eggs, and 3 to 6 aleurone rolls. He allows from 3 to 4 glasses of red wine and some green vegetables. For the customary dry vegetables—peas, haricots, beans—may be substituted soy beans, which are very rich in albumin and poor in starch, but they are difficult to cook. This regimen is usually preferred by the patients to one of oatmeal and milk; it is more satisfying and causes neither constipation nor diarrhœa. The treatment must be followed at least three days—often much longer. The glycosuria does not rise higher than with an ordinary mixed diet in which the carbohydrates have been reduced to the inevitable minimum. Occasionally it falls even lower, and sometimes it disappears completely, when the previously named diets have remained ineffective in that respect. Dr. Labbé thinks that the starch, as well as the albumin, of dry vegetables is better assimilated in diabetics than those of other foods. This regimen is said to overcome the nitrogenous denutrition and emaciation, to cause the disappearance of the insomnia and anorexia, and to obviate the danger of coma. It diminishes urinary acidity and diaceturia and affords a minimum of acetonuria. These results appear to be dependent on the peculiar chemical properties of leguminous albumin and starch, assimilation of which seems to take place under conditions different from those obtaining for cereals.

Institutes of Puericulture.

The directorate of the Assistance Publique has ordered the establishment of 11 institutes of puericulture in the hospitals. Two years ago such an institute was established by a decree of the Prefect of the Department of the Seine, acting on a resolution of the general and municipal councils, at the Hospice des Enfants Assistés in the service of Dr. Variot. The decree was, however, quashed by the Conseil d'État as not complying with legal requirements. On the other hand, as courses in infant hygiene and infant consultations exist in a large number of hospitals, the administration of the Assistance Publique was unwilling to accept this unique institute, which would seem to enjoy a kind of monopoly and which it had had no direct part in initiating. The new decree establishes 11 such institutes, which are chiefly, however, rather a transformation of the infant consultations already existing in the obstetrical services of the hospitals, with the exception of that of Dr. Variot, which is a true pædiatric clinic. These institutes are to be opened in the services of Professor Ribemont-Dessaigne at the Beaujon, Professor Bar at the Tarnier clinic, Dr. Doléris at St. Antoine, Dr. Variot at the Hospice des Enfants Assistés, Dr. Bonnaire at the Maternité, Dr. Boissard at the Lariboisière, Dr. Lepage at the Boucicaut, Dr. Tissier at the Charité, Dr. Potocki at the Pitié, Dr. Demelin at St. Louis, and Dr. Bouffe at the Tenon. On the medical and obstetrical *chefs de service* is imposed the duty of the teaching and the charge of the infant consultations. No special remuneration is attached thereto. The *chefs de service* charged with the control of an Institute of Puericulture are to make to the Administration a yearly report on its working, the number and dates of the consultations, the number of children examined, the number of students who have taken the course, the quantities of milk distributed, and so forth.

The Campaign against Alcoholic Beverages.

Under the name of "L'Alarme" there has been established in Paris an Anti-alcoholic Committee to organise in the principal towns of France before the next election a series of meetings against the use of alcoholic drinks. This committee, presided over by M. Henri Schmidt, a deputy for the Vosges, has received the patronage of many eminent politicians from varying localities. Without taking any active part in the political contests the committee will call upon the electors to insist that their respective candidates shall make necessary anti-alcoholic reforms a part of their programmes. The first meeting was held on Jan. 18th at Nancy, and M. Henri Schmidt and Dr. Lucien Jacquet, physician to the Hôpital St. Antoine, were among the speakers.

Antityphoid Inoculation.

Dr. Lajoanio, médecin-major of the 7th Battalion of Chasseurs Alpins, has presented to the Académie de Médecine a communication of great significance regarding the polyvalent vaccine prepared by Professor Vincent at the School of Military Medicine at Val-de-Grâce. This regiment for 18 months under the torrid sun of Morocco had to sustain repeated attacks by day and night from the Moroccan troops. All around malaria, dysentery, and typhoid fever were decimating the troops. The first two of these diseases did not spare the 7th Chasseurs, but not one of its vaccinated men took typhoid fever, and further proof that the vaccination was the effective agent in prevention lies in the fact that the only two men who contracted the fever were two who had not been vaccinated because, as they had had typhoid some years before, vaccination was not considered necessary in their case. This study further shows that the strains of typhoid bacilli in Morocco are of particular virulence, for the instances in which military men and civilians who had previously had the disease contracted it afresh in a severe form in Morocco were numerous. Typhoid fever raged furiously in Morocco during 1912, for it attacked 170 per 1000 among the unvaccinated. The experience shows the value of Vincent's vaccine, which is a polyvalent vaccine prepared from many strains of bacilli.

The Treatment of Leishmaniasis by Ehrlich's Method.

At the Société de Dermatologie Dr. Jeanselme reported the good results obtained from salvarsan in a patient attacked with Biskra boils. He was a young assistant medical officer who had been on campaign for a year in the oases of Southern Algeria. He contracted the disease at Biskra in September last and returned to France on Oct. 10th. The first boil made its appearance from 12 to 15 days later. In two months ten new foci had developed. As this disease is undoubtedly due to leishmaniasis, and as M. Nicolle and M. Manceau had already obtained encouraging results in that disease with arsenical treatment, M. Jeanselme, after satisfying himself that the Wassermann reaction was negative, gave three intravenous injections of neosalvarsan and two of salvarsan. A complete cure ensued in 20 days. This is the most energetic treatment yet found against this disease.

Jan. 19th.

VIENNA.

End of the Conflict between the Sick Clubs and their Medical Officers.

AFTER having continued for more than a year the conflict between the Austrian Krankenkassen, or sick clubs and friendly societies, on the one hand, and their medical officers on the other, has come to an end which shows no victors nor vanquished. The chief point of discussion was lately the dismissal of those practitioners who had accepted positions as medical officers appointed by the clubs in spite of the boycott proclaimed in regard to these appointments by the organisation of practitioners in Lower Austria. The clubs had procured their services by offering high salaries, and had had to make long contracts with them. Now the united medical profession has demanded their dismissal as a protection against the importation of non-unionists in any similar dispute which may take place in time to come. After protracted negotiations, which were broken off more than once, for both parties were indisposed to give way on this particular point, the efforts of the Government brought about a compromise acceptable to both sides. The non-unionist medical officers might remain, but those who had refused to work on the old conditions had all to be reappointed, so that the sick clubs have now to pay not only their former medical officers, but also the substitutes whom they had employed at great expense, although the services of these latter are now absolutely superfluous. Furthermore, 200 new appointments have to be made within two years, and the remuneration will be either on the basis of so much per patient in small districts with less than 1000 members or for a fixed sum which must average at least 5 kronen for each insured member, surgical operations and midwifery to be extras. The contracts will be made under the supervision of the above-mentioned medical unions, with due consideration for the kind of work in the respective districts. The control of the medical work will be effected only by medical men—hitherto it has not been always so—but the controlling agents shall not be entitled to alter the treatment or to dismiss a patient from the sick list unless the regular medical attendant takes a similar view of the case. Altogether, the profession although it has not accomplished all its intentions, may be well satisfied with the results obtained, and there is no doubt that this first successful outcome of a serious conflict between a large medical body and the sick clubs will have a most beneficial effect on all future disputes, as showing the Krankenkassen that their authority has its limitations.

Sexual Diseases amongst University Students.

The Austrian Society for Combating Sexual Diseases has made a remarkable advance in its endeavours to eradicate the scourge of sexual diseases by establishing a special ambulatorium at which students of the Vienna universities are the only patients. The attention of the principal promoters of the objects of the society was drawn to the fact that so many men engaged in the "free" vocations were victims of gonorrhœa and syphilis, which they had acquired between the ages of 20 and 25 years, while they were students at the university. They are often ashamed or afraid to go to a regular practitioner for treatment, preferring to rely upon the knowledge of some friend or the advice of some quack to cure their illness. Therefore the society at once started the above-mentioned ambulatorium with a competent specialist at the head of it, and the recently published report for the first seven months of its existence shows that 482 patients applied for advice and made 3968 attendances. There were 31 cases of syphilis, 268 of gonorrhœa, 12 of soft sore, and the remainder either suffered from some other complaint or had no illness at all. The attendances at the ambulatorium increased up to as many as 59 patients per day. In the later months the ambulatorium was also attended by students of "gymnasia," or what we call Latin schools (boys from 10 to 18 years); from these schools there came to the institute about 39 patients aged between 15 and 19 years. Even these figures show that such an institute is a necessity here, for it must be kept in mind that the real number of affected youths and university students is considerably in excess of the figures given above, because it is not yet generally known among them that there exists a special ambulatorium where help and advice are provided for them in a spirit of philanthropy.

Jan. 19th.

ITALY.

Professor Murri.

A GREAT demonstration was made to Professor Murri at his lecture to inaugurate the new academic year. The ceremony was one of especial importance as the first public appearance of Professor Murri since his serious illness last summer. The hall was packed with an audience of students of all the faculties of the university, professors, ex-pupils, and the notabilities of the city of Bologna. His entrance was greeted with a triple round of applause and addresses of congratulation were offered, first by one of the medical students, then by one of the professors of the Medical Faculty, and lastly by the President of the Association of Medici Condotti. Professor Murri, who appeared in the best of health, after thanking his audience for his reception, gave a brilliant address, in which he emphasised the undiminished importance of the inductive method in medicine.

The Agitation of the Doctors of the Hospitals in Rome.

Professor Bastianelli, as president of the section of Medici Ospedalieri in Rome, was able to announce to a crowded meeting last month the satisfactory solution of a number of the questions which interest in the closest manner the welfare of the doctors of the Roman hospitals. A commission nominated by the section to confer with the Royal Commissary, Comm. Gajeri, had come to an agreement with him on a number of important points, such as the right of the doctors to treatment in hospital and their claim to a day's rest each week. On the much vexed question of the tax upon application for appointments the Royal Commissary had expressed his willingness to reduce the amount from lire 200 to lire 10 or 15, but the meeting refused to accept this concession, preferring to contest the legality of the imposition of a tax at all.

Foreign Doctors in Italy.

The council of the federation of the Ordini dei Medici at a recent meeting discussed the ever recurrent theme of the foreign doctors. The Order of Porto Maurizio raised the question of the facility with which foreign doctors could obtain the *rivalida* of their diplomas, and hence the right to practise freely in Italy. The council decided to call once more the attention of the medical faculties of Italy to the necessity of being very severe and careful in the concession of the *rivalida* for the due protection of the Italian medical profession, and especially in defence of the dignity of Italian science.

Medical Biography.

The Istituto Micrografico Italiano is bringing out under the auspices of the Società Italiana di Storia Critica della Medicina e delle Scienze Naturali a series of lives of celebrated Italian physicians and naturalists. The first volume, upon the life and work of Bartolomeo Eustachi, has just been issued. It is a small book of 80 pages and is published at 1 lira. Others promised include Valsalva, Morgagni, and Aulus Cornelius Celsus.

Jan. 15th.

SOUTH AFRICA.

Medical Department, South African Defence Force.

Regulations providing for a Medical Department of the South African Defence Force have just been promulgated. The Department is to consist of three sections, the Permanent Force Section, the Citizen Force Section, and a Voluntary Aid Section.

The Permanent Force Section is to consist of a staff officer for medical services at defence headquarters, a medical officer in charge of a medical training school, staff medical officers, including medical staff quartermasters and subordinate staff—viz., hospital staff sergeant-majors, hospital staff sergeants, hospital sergeants, hospital corporals, and hospital orderlies. Officers of the Medical Department are to be members of the Permanent Force (staff), and will be graded as first, second, or third grade staff officers with the pay assigned to those grades, and rank as follows: First grade, major or lieutenant-colonel; second grade, captain or major; third grade, lieutenant or captain. The staff officer for medical services may also be required to undertake the duties of an assistant medical officer of health for the Union on such conditions and at such rate of emoluments as the Government may decide. Medical staff quartermasters will be first class or second class with pay accordingly. Those of the first class are to hold the rank of captain; of the second class the rank of lieutenant. The subordinate staff will be recruited as far as practicable from the non-commissioned ranks of the Permanent Force, any of whom below the rank of sergeant, after undergoing a prescribed course of instruction in medical duties, may be required to serve for one year as hospital orderlies, one year as hospital corporals, making a total of two years in the Medical Department, and three years as hospital sergeants. Appointments as hospital sergeant-majors will be made from those hospital sergeants who have passed a qualifying examination for the higher appointment, and these will have the rank of warrant officers. Hospital orderlies and corporals who are returned to regimental duty, at the conclusion of their periods of appointment as such, may receive medical staff pay (non-pensionable) at the rate of 6*d.* a day so long as they hold regimental rank not higher than corporal and provided they come up for, and qualify annually at, a refresher course of medical training.

The scheme sounds well enough, but is not difficult to criticise. First, the force is to be under a lay officer, the Inspector-General, who, although doubtless guided by the staff officer for medical services, cannot be expected to appreciate medical needs or requirements, and apparently even his adviser may at any moment be taken away from him to act as an assistant medical officer of health for the Union. In the second place it must to great extent be a paper force, for the Permanent Defence Force are really mounted policemen scattered throughout the frontier districts of the Union. At any rate, the five regiments are so broken up into small units that there will seldom be any considerable aggregation of its members except in time of civil commotion or war—certainly not enough at any time to warrant the establishment of a military hospital for the sick and the training of orderlies and hospital officers of different grades.

The citizen force section is apparently "on its own" in each district, and is directly under the Commandant General, who presumably will be advised also by the staff officer for medical services. It provides for an assistant director of medical services being appointed for each military district or for a group of military districts to take command and supervise the technical training of the *personnel* and units of the Citizen Force Section detailed for medical services in that district or group of districts, and to advise as required upon all matters connected with the medical and sanitation services of the Coast Garrison and Citizen Forces in that district. Deputy assistant directors of medical services may be appointed for any military district or subdivision thereof as sanitation officers, and to assist generally the assistant directors in their duties. Assistant directors may be granted the rank of lieutenant-colonel, deputy assistants the rank of major. Except in case of appointments as assistant and deputy assistant directors of medical services, first appointments to commissions as medical officers will be made to the rank of captain. In no case is a person to be eligible for appointment as a medical officer unless he is registered under one of the Medical Acts in force in the Union and is between the ages of 21 and 35 years. Within two years of first appointment a medical officer will be required to attend at the medical training school for a period of one month, during which a course in the following subjects will be undergone: the South Africa Defence Act and regulations framed thereunder and the Union military discipline code, the duties and powers of medical officers, medical organisation, administration and equipment, map-reading and elementary tactics, military sanitation, and Part 4 Royal Army Medical Corps Training. Promotion examinations in other than professional subjects will have to be passed before captains can be promoted to majors, and promotion to the rank of lieutenant-colonel will only be given when there are vacancies on the establishment of that rank, and will be made by selection from the rank of majors who have qualified for that rank by examination. Any medical practitioner is eligible to serve in the Reserve of Officers without having previously held commissioned rank, and on appointment he may be given such rank not below the rank of captain as may be considered suitable to his position and standing. Officers will draw the pay and allowances of their rank as prescribed in the regulations for pay and allowances, Active Citizen Force. During periods of continuous training and on such other occasions as may be authorised by the Minister, medical officers may draw, in addition to any pay or allowance due to them under those regulations, a medical staff allowance at the rate of £1 10s. per diem, presumably to cover the cost of a locumtenent. During attendance at special courses at the medical training school or elsewhere medical staff allowance at one half of this rate may be granted, provided the prescribed certificates are obtained. The provisions generally for the Citizen Force section are very elaborate and may or may not prove workable, but the general opinion that is held amongst those competent to judge is that they are unsuitable for South Africa.

Appointments in Permanent Force: Medical Department.

Dr. P. G. Stock, formerly assistant medical officer of health of Johannesburg, has been appointed Staff Officer for Medical Services, with the rank of Major. Lieutenant-Colonel G. H. Knapp, formerly principal medical officer, Cape Colonial Forces, has [illegible] Colonel in the Medical [illegible] rce, whilst Surgeon- [illegible] in the Cape Mounted Rifles, and Staff-Surgeon H. R. Brown, of the Natal Police, are appointed Captains in the same department.

Dec. 15th, 1913.

Obituary.

HENRY ALBERT REEVES, F.R.C.S. EDIN.

THE death occurred on Jan. 16th, at the age of 73, of Mr. Henry Albert Reeves, late of Grosvenor-street, London, W., formerly assistant surgeon at the [illegible] to the Royal Orthopæ[illegible] the Hospital for Wo[illegible] Hospital for Women and Children, Shadwell.

Mr. Reeves's best work, both general and special, was done some years ago, and his name, save to those acquainted with his writings, is now no longer familiar. But in his day he was a well-known operating surgeon. His "Human Morphology," published in 1879, was said by the *Saturday Review* to be the "finest book ever published on the subject in this or any language," and his "Bodily Deformities" is also a notable work. In operative surgery (he was ambidextrous) he attained to high proficiency, and when he finally concentrated on orthopædics, resigning all other appointments to do so, he was recognised as an authority on the subject. But differences of opinion at the Royal Orthopædic Hospital as to selling the site and amalgamating with the Orthopædic Hospital in Great Portland-street, of which he strongly disapproved, led to the severing of his connexion with this institution, much to its loss, as, apart from his skill, he was greatly loved by his patients, especially those of the poorer classes.

A personal friend writes: "Mr. Reeves was always a lover of books, and gradually he abandoned himself almost entirely to their study. With an immense library, in five different languages, to which he was constantly adding, few scientific and thoughtful books that were published did not come under his ken, and in his search for truth possibly his investigations covered too vast a field for his own advantage. But his erudition was enormous, and latterly he had devoted his whole attention to a scientific study and sifting of all the religions of the world, of which he probably knew as much as any man living, and his book on the subject was almost ready for publication when it was stopped by the illness that attacked him a year ago and ended fatally last week."

Mr. Reeves was married to the well-known novelist, Helen Mathers.

ALEXANDER S. L. NEWINGTON, M.B. CANTAB., M.R.C.S. ENG.

ON Jan. 17th, while driving his car near Ticehurst, Sussex, Dr. Alexander Newington met with an accident and sustained injuries which were rapidly fatal. He had put the brakes hard on to avoid colliding with a motor-dray and the skid threw him from his seat into the road upon his head.

Alexander Samuel Lysaght Newington was born in 1846, the son of Dr. Samuel Newington. His grandfather was the founder of the well-known private asylum for the insane at Ticehurst, and his father succeeded in due course to its management. He was educated at Bromsgrove School and as a lad went to India as a planter, but after five years [illegible] won many prizes. Proceeding to St. Thomas's Hospital he qualified as M.R.C.S. in 1874, and became house physician to the famous Murchison. In the following year he took the degree of M.B. Cantab., and settled down in a village practice in Oxfordshire. About the same date he married Gertrude, eldest daughter of the late Dr. Robert Barnes, one of the leading obstetricians of that day.

A few years later, in the early "eighties," Dr. Alexander Newington returned to Ticehurst as physician to his father's asylum, and from that time until his death he remained associated with it. At one time a brother, Mr. Theodore Newington, was also on the medical staff there, but latterly Dr. Alexander Newington and his cousin, Mr. H. F. Hayes Newington, have been the joint proprietors of, and physicians to, the asylum.

Dr. Alexander Newington had been an enthusiastic motorist since the earliest days, and was among the first medical men in this country to own a car. His interest in this subject was always keen, and he had a thorough knowledge of the mechanism and design of cars, acquired in the days when road repairs were an almost daily necessity. He was a most experienced driver. He contributed little to professional literature, but his hereditary bent towards alienism was shown by his choice of a subject for a graduation thesis—puerperal insanity. Mrs. Newington survives him; there is no issue of the marriage.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. E. Ponfick, of Breslau, Privy Medical Councillor.—Dr. E. Cohn, of Frankfort, Privy Medical Councillor.—Dr. T. H. Knoll, of Aix-la-Chapelle, Sanitary Councillor.—Dr. John G. Cecil, formerly professor of medicine in the University of Louisville.—Dr. A. Tesson, formerly professor of chemistry and toxicology in the Angers Medical School.—Dr. E. Baudrimont, formerly surgeon to the Bordeaux hospitals—Dr. Gustav Pfalz, *docent* of ophthalmology in the Medical Academy of Düsseldorf and president of the Rhine Medical Association, aged 55.—Dr. Hans [illegible]
medicine in the University of [illegible]
Thorn, Privy Medical Councillo[illegible]
German Medical Association, a [illegible]

the tissues puts out of court the more radical treatment, which will be required later in the event of the survival of the patient.

I am, Sir, yours faithfully,
Plymouth, Jan. 17th, 1914. C. HAMILTON WHITEFORD.

To the Editor of THE LANCET.

SIR,—I am very much interested in everything that my friend Mr. Edred Corner writes, and this is especially so with regard to his paper in THE LANCET of Jan. 10th. I must say that on this occasion I am surprised to find that he has had such good results in the treatment of gastric and duodenal perforation by the method he describes. However, I know that there are very many ways of attaining the same end, and though I do not propose to try his method I shall watch with great interest the results in his own hands.

There is just one sentence, however, to which I must draw attention, but only to sound a note of warning. Mr. Corner says, "Fears of more than a temporary and brief gastric fistula may be dismissed." In my experience gastric and duodenal fistulæ are very serious complications indeed, and I have seen several cases in which they have rapidly led to the death of the patient. As this method is put forward as especially useful for those with limited experience in surgery I think it most important to draw attention to this aspect of the matter, because, though Mr. Corner has been successful in a series of cases (he does not say how many), I feel quite confident that if this method is at all widely practised it will be followed by many fatalities from gastric and duodenal fistula.

In his summary Mr. Corner says that in the hands of experienced and facile operators the excision of the ulcer followed by suture of the wound, &c., may be better and result in the recovery of the patient. This rather presupposes that excision of the ulcer is a necessary part of the operation for perforation, but this is certainly not so, and in my series up to date (76 cases of gastric and duodenal perforation with 15 deaths) I have only twice excised the ulcer during the course of an operation for perforation.

Closure of the ulcer by suture may take more time than the method which Mr. Corner describes, but I shall be very much surprised if it does not turn out to be by far the safer method, and therefore attended with a smaller mortality.

Most writers on this subject speak of the need of saving time in the operation, but I always feel that it is much better to spend a little extra time on the operating table than to express regrets at the post-mortem table. I doubt if a patient often dies because of the extra time spent in careful suturing, but I am quite sure that they very often die for the want of care in the performance of emergency operations.

I should like very much to know how long it takes Mr. Corner to do this operation. I must confess that the treatment of a simple perforated gastric or duodenal ulcer with irrigation of the peritoneum—in which I believe—takes me 30 or 35 minutes, while in those few cases in which I think it wise to perform gastro-enterostomy at the same time the operation occupies from 45 minutes to an hour, and in difficult cases perhaps a quarter of an hour longer. I am, Sir, yours faithfully,

Newcastle upon Tyne, Jan. 12th, 1914. G. GREY TURNER.

THE STERILISATION OF MILK AND ALLIED QUESTIONS.

To the Editor of THE LANCET.

SIR,—It would be a very regrettable circumstance if the sweeping statements expressed by Dr. R. Vincent in THE LANCET of Jan. 17th on the above subject were to be accepted as representative of present-day medical opinion. In his letter he refers to the "appalling" results of feeding children on cooked milk.

As chairman of the Association of Infant Consultations and Schools for Mothers—an association to which some hundred local societies are affiliated—I am in constant touch with a large number of medical officers and superintendents of centres to which a very considerable number of healthy infants are brought for advice and treatment, and I may say that the vast majority of these medical men and officials hold views diametrically opposed to those of Dr. Vincent. We receive reports also from a very large number of infant consultations which are not affiliated to the central association, and some of the best results of which we have records are from those consultations at which desiccated milks are exclusively used for the artificial feeding of infants, and desiccated milks are milks which have been submitted to a somewhat severe cooking process. In Marylebone the infant death-rate has fallen in 13 years from 190 per 1000 births to well below 100, and during this period, owing to the active campaign carried on by the municipal authorities and the local health society, the use of unboiled milk has been reduced almost to the point of extinction. The fall in the tuberculosis rate has been equally sensational. Could these results be if cooked milk were the unmitigated evil Dr. Vincent would have us believe?

I am at present engaged in re-examining the old cases who have passed through my infant consultations, some as long ago as 1906. I am quite surprised to see how favourably the children who were reared on boiled milk compare with the average London child of the same age; and, indeed, with many of the exclusively breast-fed children of the same age who also attended at the consultations.

Personally, I hold no brief for cooked milk. When good fresh milk can be guaranteed I see no reason why it should be boiled, and I frequently order it for patients who can afford to buy it. But I can distinguish no difference, judged by any criterion with which I am acquainted, whereby infants fed on raw milk can be distinguished from those fed on cooked milk, although I could very easily pick out a group of selected cases from either class which might be made to prove the case which ever way I desired.

In view of the discovery of the vitamines, and in view of the great progress recently made in the fundamentals of nutrition, it surely is an anachronism to write vaguely about "mysterious diseases" in children which baffle their own doctors, but which are at once explicable to Dr. Vincent in the terms of cooked milk. In America, the home of certified milk, not only are the original and most fervent pioneers of this movement now converted to pasteurisation, but they are among the most active agitators for the pasteurisation even of certified milk of the highest grade. In conclusion, I would quote a translation from Professor Porcher's recent book "Le Lait Desséché" (p. 86): "At a certain infant clinic in Belgium the infant mortality rate was 260 in 1901. In the year 1903 sterilised milk was introduced, and the rate fell to 150. In 1907 trained health visitors were employed and the rate further fell to 60 per thousand. In the year 1908 dried milk was substituted for sterilised milk and the rate fell to 34 per thousand." Facts of this kind—and, thanks to the work of infant consultations, they are daily becoming more common—are more eloquent than pious opinions.

I am, Sir, yours faithfully,

Harley-street, W., Jan. 15th, 1914. ERIC PRITCHARD.

To the Editor of THE LANCET.

SIR,—May I add my humble experience to the weighty evidence presented by Dr. Ralph Vincent in favour of the raw-milk feeding of infants?

My attention was first drawn to the subject during a very severe epidemic of diarrhœa in Mid-Kent some 24 or 25 years ago. I was then led to suspect that boiled-milk feeding had a good deal to do with the incidence and fatality of the complaint, and ever since have been a convinced opponent of boiled and advocate of raw milk as a diet for both children and adults. Needless to say, I have in consequence been "up against" general professional opinion, and more especially against almost universal medical officer of health opinion, but this I have, though with some loss in fees and credit, to my private entire satisfaction completely disregarded. The improved health following the change of diet has been so immediate and pronounced that usually there has been no need to prescribe anything else, and a single consultation has often sufficed to effect a cure. In no case have bad effects followed, and in no single instance has a previously non-tuberculous infant, in which the raw milk *régime* was carried out with reasonable care, been known by me to have afterwards developed signs of tubercle. It is no small gratification to me to find that Dr. Vincent has been able, at least in part, to supply the rationale of a treatment which I had adopted so long ago on grounds of clinical observation alone.

I am, Sir, yours faithfully,

Stoke Newington, N., Jan. 16th, 1914. I. B. MUIRHEAD.

LISTERISM IN LONDON IN THE "SEVENTIES."

To the Editor of THE LANCET.

SIR,—I have just finished reading the admirable "Life of Lord Lister," by my friend Dr. G. T. Wrench. He speaks of the apathy with which Lister's teaching was received and of the slow progress it made, especially in London. My teacher, Sir Henry Howse, like many great teachers and workers, wrote little, and seldom took part in discussions; further, he is very rarely seen in London nowadays, so that his pioneer work in the introduction of Lister's methods into London is unknown to the majority of your readers and unmentioned by Dr. Wrench.

Sir Henry Howse was appointed assistant surgeon to Guy's Hospital in the early part of 1870; he at once went to Edinburgh, studied Lister's methods, came back, and introduced them into Guy's Hospital in the same year—that is, a year before Lister's address at Plymouth in 1871. In 1871 Mr. Davies-Colley was appointed assistant surgeon; he, seeing the excellent results in Sir Henry Howse's wards, adopted Lister's treatment, as did all the assistant surgeons subsequently appointed. Sir Henry Howse became a full surgeon in 1874, with the care of over 60 patients, so that then all of these and all those in the beds of the assistant surgeons were treated rigidly with Lister's methods. I have recently had a letter from Sir Henry Howse in which he says that in 1867, when he was house surgeon, he began in a small way trying the methods which were published by Professor Lister, then at Glasgow. I think that these facts will, as Sir Henry Howse says, "answer, at any rate as far as one hospital is concerned, the assertion that London surgeons were slow to avail themselves of the advantage of Listerism."

Your readers will, I am sure, excuse the following quotation from Sir Henry Howse's letter. It is of historical interest:—

> In the year 1871 and for the two or three years following ...... Davies-Colley and myself were the only assistant surgeons in the hospital. According to the hospital rules we had the charge of the erysipelas wards, to which all the erysipelas and severe septic cases occurring in the general wards were transferred as they arose. We had sole charge of all these cases as well as of a certain number of beds in the general wards. In the erysipelas wards we had often to do amputations and other severe operations in beds surrounded by most highly infectious erysipelas cases and by severe septic cases such as gangrene and urinary extravasation. It was a discovery, it was a most remarkable phenomenon to us to find that we could operate on these cases in the erysipelas wards with the spray and antiseptic dressings as safely as we could in the general wards or even in private rooms. After this discovery the erysipelas wards rapidly changed their character, and from being deadly wards became almost like the other wards at the hospital. The general wards themselves underwent the same change for the better. I may cite one particular case in my own experience. I took over Naaman Ward from Mr. Cock on his resignation. From the nature of his practice he had always in it a much larger proportion of urinary cases (extravasation and such like, many of them the most offensive possible), and Naaman Ward bore in the hospital an exceedingly bad reputation. I was even advised not to take the ward as I had the choice to take some other. I had, however, by this time firmly established in my own mind the safety of the antiseptic treatment of wounds, and felt convinced that I could make Naaman as healthy as any other ward in the hospital. This was accomplished, and many old house surgeons and dressers must remember that I operated there as freely and successfully as in any other ward.

I am sorry to have troubled you with so long a letter, but I feel your readers ought to know Sir Henry Howse's pioneer work, and will be glad to have this addition to the large amount of information given in Dr. Wrench's book, especially as it softens a little the severity of its indictment against the London surgeons in the "seventies."

I am, Sir, yours faithfully,

Jan. 15th, 1914. W. HALE WHITE.

QUININE POISONING: A PERSONAL CASE.

To the Editor of THE LANCET.

SIR,—Seeing in THE LANCET of Jan. 17th Mr. J. D. Gimlette's account of three cases of poisoning by excessive doses of quinine, it has occurred to me that some account of a similar personal experience may be of interest to the profession. It must necessarily be most egoistical. At 8.30 A.M., Sept. 22nd, 1913, I had occasion to take, for pyrexia and malaise, 10 grains of quinine sulphate. I invariably take this in an effervescing solution which I keep made up in a concentrated solution of 10 grains to the drachm, with citric acid. On this occasion what happened was that I forgot the concentration and helped myself to at least a generous ounce of the solution—i.e., unknowingly I took probably 100 grains of quinine be selected what becomes of the mediocrity of the profession? Are they to compete outside with the State doctors? The choice of an intelligent patient of his own doctor is at least as good as that made usually by a public board on his behalf. In either case a mistake can be made and often is, but it can be corrected much more readily in the former than the latter case.

In the picture Sir John Collie draws of a National Medical Service, it is easy to detect a glamour similar to that thrown on their pictures by confessed socialists when endeavouring to point out the advantages of the socialistic state. Sir John Collie says the changes he proposes will be to many practitioners "highly distasteful." I must reckon myself among that number, but not simply because the changes are "distasteful," but because in my opinion they are bad both for the public and the profession. If I believed in Socialism, that is in the State undertaking everything for everybody, and individual enterprise and independence being relegated more and more to the background, it might be otherwise. As it is, I regard honest competition with one's fellows, with all its drawbacks, as a more honourable position for a medical practitioner than to become a unit in any National Medical Service; and I am of opinion that medical science will be best promoted, and the welfare of the nation best maintained in the future, as in the past, by an independent profession of medicine. I am, Sir, yours faithfully,

Hackney-road, N.E., Jan. 18th, 1914. MAJOR GREENWOOD.

THE TREATMENT OF GRANULAR KIDNEY.

To the Editor of THE LANCET.

SIR,—I regret that owing to my not having been able to get the corrected proof of my letter on this subject[1] returned to the offices of THE LANCET in time for the press an error has crept in. Where the letter (in the second line from the top of the right hand column of page 210) states "in 24 hours the pulse was 94," it ought to read "in 48 hours," &c.—I am, Sir, yours faithfully,

A. GRAHAM-STEWART.

Cliftonville, Margate, Jan. 19th, 1914.

---

[1] THE LANCET, Jan. 17th, 1914, p. 209.

ROYAL ANTHROPOLOGICAL INSTITUTE. — The president and council of the institute will entertain Professor Baldwin Spencer, C.M.G., F.R.S., of Melbourne University, at a complimentary dinner at the Café Monico, London, W., on Jan. 27th, at 6.30 P.M.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of directors of this society was held on Jan. 14th, Dr. Rigden, senior vice-president present, being in the chair. Fifteen members of the court were present. Since the last court two of the vice-presidents of the society had died—Dr. Clement Godson and Mr. H. W. Kiallmark. One of the widows in receipt of grants had also died; she came on the funds in 1875, and received in grants the sum of £2300. Her husband had paid in subscriptions £37 16*s*. The sum of £1260 was voted to pay the usual half-yearly grants to the widows and orphans, and £392 10*s*. were voted for special grants to be paid out of the Brickwell Fund. The invested funds of the society now amount to £139,500. Membership of the society is open to any registered medical practitioner who at the time of his election is resident within a 20-mile radius of Charing Cross. The annual subscription is 2 guineas. Special terms for life membership. Further particulars and application forms for membership may be obtained by applying to the secretary at the office of the society, 11, Chandos-street, Cavendish-square, London, W.

THE NATIONAL INSURANCE ACT.

THE STATE MEDICAL SERVICE QUESTION.

IN delivering the first of a series of lectures arranged by the Faculty of Insurance, dealing with various aspects of National Insurance, Sir John Collie took as his subject "The Medical Profession and National Insurance," and after criticising severely what he indicated as the defects of medical service under the panel system, advocated strongly recourse to a National Medical Service as a remedy. Sir John Collie regarded as a mistake the admission to the panels of all proposing themselves, irrespective of character and qualifications. He spoke of men who had never established themselves in practices of any value as having now large numbers of insured patients, and contrasted with this system that which provided practitioners for the army and navy, and for appointments such as those offered by the Poor-law Service or the Post Office. He also called attention to the competition between medical men which was encouraged by the system, and referred to it as producing touting and other unprofessional practices. He was of the opinion that excessively large panel lists were producing scamped and inferior work, giving as an instance the experience of a panel practitioner who had told him that he had to see 50 or 60 patients every evening. He considered that a State Medical Service was the best remedy for this state of affairs and the best means for bringing the advantages of medical science within the reach of the insured. He considered that such a service would be more economical than the present system, and that without interfering with private practice would offer opportunities to those in its lower ranks to rise to eminence, its members doing their best to keep themselves abreast of modern science. We referred in a leading article last week to one great argument against a State Medical Service—at any rate, in the present position of medical practice. When the combination of a choice of doctor by the insured with a regimented service is considered, the path advocated by Sir John Collie is seen to be difficult, while some of his criticisms on the working of the Act are being directly contradicted.

MEDICAL REFEREES AS UNDERSTOOD BY SOME APPROVED SOCIETIES.

A letter to the *Daily News* recently recommended the formation of "complaints committees" as a solution of "the difficulty as regards satisfactory attendance by panel doctors," and went on to call attention, surely somewhat inconsequently, to a practice for which panel doctors are in no way responsible. According to the writer "a large number of persons who have claimed sick pay on the certificate of their panel doctor are sent to another medical gentleman appointed by the Approved Society. The panel doctor says the person is unfit for work. The referee examines the patient and reports to the society that the person is not unfit." The writer, after illustrating the hardship which is thus inflicted upon the sick person by reference to an instance which occurred within his knowledge, continues: "This is happening all over the country. Whose word are we to take—that of the panel doctor who administers to the patient, or the referee appointed by the society?" The point raised is a very important one. It was referred to in THE LANCET of Dec. 13th last, p. 1734, in connexion with a case which occurred at Birkenhead. At Walsall the wholesale summoning of the sick members of a society to present themselves for examination by the medical officer of the society has been inquired into by the Insurance Committee, which passed unanimously the following resolution:—

> That this meeting registers a strong protest against the treatment meted out to the sick members of the Royal Liver Society on Thursday, Nov. 13th, when the whole of the sick members of that society were directed to attend in the space of two hours for the purpose of examination by the medical officer of the society, and that the whole facts, as brought before this meeting, be laid before the Insurance Commissioners in London.

It will be seen from the above that in some Approved Societies, at any rate, the zeal of their officials to conserve their funds is liable to inflict great hardships upon their sick members, and that the principles which should govern the appointment and calling in of a medical referee are entirely misunderstood. The matter is one which concerns all medical men engaged upon panel practice, and in its ethical aspects should be carefully considered by such practitioners as may be invited to act as referees by Approved Societies.

THE NATIONAL INSURANCE ACT AND MIDWIVES.

A legal correspondent writes: "A letter in THE LANCET of Jan. 17th, p. 213, suggested the application of part of the unallotted fund to paying medical men called in upon the advice of a midwife under the provisions of the Midwives Act. This hardly seems possible in view of the fact that the National Insurance Act, 1913, repeals the portion of Section 18 of the original Act, which permitted the fee of the medical practitioner in the circumstances indicated to be recoverable as part of the maternity benefit."

A CENTRAL PANEL COUNCIL FOR LONDON.

We have been requested by Dr. J. Hanna McBurney, 530, Fulham Palace-road, London, S.W., and Mr. Robert J. Farman, 130, Upper Kennington-lane, London, S.E., as temporary honorary secretaries of a movement for the formation of a Central Panel Council for London, to publish the following:—

> With the view to advancing the organisation of the Central Panel Council another stage a conference was held on Jan. 17th.
>
> It will be remembered that a meeting was held on Dec. 18th, 1913, at Caxton Hall, when the following resolutions were adopted:—
>
> 1. That a central body be formed to link up local panel associations.
> 2. That this body be composed of two delegates from each local panel association, preferably the chairman and honorary secretary.
> 3. That the name of this body be the "Central Panel Council (London)."
> 4. That this council be financed by subscriptions from each local panel association.
>
> The conference referred to above met for the purpose of adopting definite "objects," which, if accepted by a meeting of the council to be held at an early date, will rule the policy of this organisation.
>
> These objects are as follows:—
>
> 1. To coordinate the activities of all existing local panel associations and organisations and to encourage and assist in the formation of similar organisations where such do not at present exist.
> 2. To assist in carrying out such policies as may be discussed and agreed upon in the local panel associations and upon which there appears to be general agreement.
> 3. To afford information and advice to the executive officers of the various panel organisations.
> 4. To prepare and present representations when necessary to the Commissioners, Insurance Committees, and other public bodies.
> 5. To maintain and develop in all directions an efficient medical service under the panel system.
>
> It will be seen that the constituent parts of the Central Panel Council will be the local panel organisations, whilst the individual practitioner will remain constituent to his local panel association.
>
> Although the main efforts of the Central Panel Council must at first be directed towards the consolidation of the panel profession in the metropolis, it is earnestly desired that provincial panel associations will take an early opportunity of placing themselves in communication with the honorary secretaries of the council, with a view to the extension of its operations and the coördination of panel policy in all parts of the United Kingdom.
>
> Individual practitioners are urged to at once join the local panel association in their area, and, where no such bodies exist, to form themselves into associations without delay.
>
> With the object of assisting existing associations, honorary secretaries are invited to send their names and addresses to the honorary secretaries of the council, so that a directory may be formed, and this information given to practitioners desirous of joining these bodies.

We are informed further that a meeting of the Central Panel Council for London will be held early in February. Chairmen and honorary secretaries of local panel associations are requested to communicate at once with either Dr. McBurney or Mr. Farman, so that invitations may be issued as early as possible.

THE NATIONAL INSURANCE ACT IN SUFFOLK.

In a recent article dealing with the past year's work under the National Insurance Act, the *East Anglian Daily Times* expressed great satisfaction at the success which has been achieved in the district which it represents. In particular it dwelt upon the relief afforded to women workers and upon the advantages of sanatorium benefit, together with the appreciation of what has been done for them expressed by the insured persons of both sexes who have received medical and sickness benefit. It may be noted that although the article admits that the same experience has not been universal among Approved Societies, it mentions the secretary of an Oddfellows lodge as having stated that so far from the Act having led to malingering in his experience, his lodge, a typical working man's lodge, had paid £90 less in sickness benefit during the past 12 months than they had paid for some years, in spite of the lodge containing 100 more members than before. It would be interesting to know in how many lodges sickness benefit has been less than the average or normal, and whether any cause accounting for this can be assigned.

NATIONAL LEAGUE FOR PHYSICAL EDUCATION AND IMPROVEMENT.—The Lord Chancellor took the chair at a dinner held on Jan. 19th at the Savoy Hotel, London, in aid of this league and of the Mansion House Council on Health and Housing. Lord Haldane proposed the prosperity of the cause which both organisations have at heart in an eloquent and discerning speech. Donations towards the objects of the league amounting to upwards of £1800 were acknowledged during the evening.

[illegible] Ann Hutchings died [illegible] house on the eve of her 103rd birthday. Her father was in his 100th year at the time of his death, and a brother died aged 103 years, and a sister aged 98 years. Mrs. Harriet Light, of Weston-super-Mare, who celebrated her 100th birthday on Sept. 13th last, died on Jan. 10th. Mrs. Cooper, of Weston-super-Mare, another centenarian, died on Jan. 7th in her 101st year. Mrs. Clarke, of Rushden, has recently died at the age of 101.

Medical News.

Dr. Karl Justi has been recognised as *privat-docent* of Pathological Anatomy, General Pathology, and Tropical Diseases.—*Heidelberg*; Dr. Karl Jaspers has been recognised as *privat-docent* of Psychiatry.—*Innsbruck*: Dr. S. von Schumacher, extraordinary professor in the Veterinary School in Vienna, has been appointed Extraordinary Professor of Embryology and Histology. Dr. A. Windaus, extraordinary professor in Freiburg, has been appointed to the chair of Medical Chemistry, in succession to Dr. Pregl.—*Kiel*: Dr. Heinrich Schade, *privat-docent* of medicine, has been granted the title of Professor. Dr. F. Stern has been recognised as *privat-docent* of Psychiatry and Neurology, and Dr. O. Aichel, of Halle, as *privat-docent* of Anatomy and Anthropology, and has been appointed a Prosector in the Anatomical Institute, in succession to Dr. K. von Korff.—*Königsberg*: Dr. Theodor Cohn, *privat-docent* of Urology, and Dr. Hermann Streit, *privat-docent* of Otology, have been granted the title of Professor.—*Lyons*: Dr. J. Lépine has been appointed Clinical Professor of Mental and Nervous Diseases.—*Marburg*: Dr. Jakob Hürter and Dr. Ludwig Kirchheim, *privat-docenten* of Medicine, have been granted the title of Professor.—*Naples*: Dr. Adolfo Ferrata, of Parma, has been recognised as *privat-docent* of Histology and Medical Chemistry.—*Rostock*: Dr. O. Bumke, extraordinary professor in Freiburg, has been appointed to the chair of Psychiatry, in succession to the late Dr. Schuchardt. Dr. Brüning, extraordinary professor of children's diseases, has been recognised as a member of the Medical Professorial Senate.—*Sienna*: Dr. Bruno Brunacci has been recognised as *privat-docent* of Physiology.—*St. Louis University School of Medicine*: Dr. Downey L. Harris has been appointed to the chair of Hygiene.—*Strasburg*: Dr. G. Gruber has been recognised as *privat-docent* of Pathological Anatomy.—*Stuttgart*: Dr. Tafel, who has travelled in Thibet and published valuable researches and observations, has been granted the title of Professor.

Society of Medical Officers of Health: School Medical Service Group.—At the third meeting of this group, held in London under the chairmanship of Dr. R. Hughes, it was resolved that the council of the parent society should be asked to take steps to include whole-time school and assistant school medical officers and medical officers whose duties include school work in the provisions of the Bill securing superannuation and security of tenure. The method of organising sub-groups of the service was discussed, but consideration of the question of approaching the Board of Education and of the relation of the school and public health services was postponed for the present. The next meeting of the group was provisionally fixed for the third week in March at the office of the parent society, 1, Upper Montague-street, Russell-square, London, W.C.—A meeting of the Midland branch group of the School Medical Service Group will be held on Saturday, Jan. 31st, at 3 P.M., at the Medical Institute, Edmund-street, Birmingham, when matters of considerable importance to the service will be discussed. Those unable to attend but desirous of joining the Midland branch group are invited to write to Dr. A. Hamilton Wood, 38, George-road, Edgbaston, Birmingham.

Medical Sickness and Accident Society.—The usual monthly meeting of the executive committee was held at 429, Strand, W.C., on Jan. 16th, Dr. F. J. Allan being in the chair. The accounts presented showed a decrease in the number and amount of sickness claims during the month of December. The new proposals received were above those for the same month in the preceding year, and on the whole year the numbers are about the same. The annual statement of accounts was presented and discussed, and showed a satisfactory improvement in the sickness branch of the society. At this meeting special attention is paid to those claimants who are certified as being permanently incapacitated. This list is a long one, and the amount paid away in 1913 to these cases was over £5000. If ever illustration was required of the necessity for such a society as this, and the comfort and boon it is to those who are unfortunately for ever laid aside from active duties, then these cases serve a striking example. Many of them frankly admit that there is nothing between them, their families, and the workhouse, except the sickness pay they are receiving from the society. The absence of worrying restrictions to all claimants is much appreciated, and this factor, combined with the regular weekly cheque, has much to do with the growing popularity of the society amongst the medical and dental professions. A prospectus and all information may be obtained from the secretary, Mr. Bertram Sutton, 33, Chancery-lane, London, W.C.

UNIVERSITY OF CAMBRIDGE: EXAMINATIONS FOR THE DIPLOMA IN PSYCHOLOGICAL MEDICINE.—The Managin [illegible] tion for [illegible] Tuesday [illegible] The examination for Part I. will be held in Cambridge; that for Part II. will be held in London.

PRESENTATION TO DR. L. A. PARRY.—At a meeting of the Brighton Division of the British Medical Association held on Jan. 16th, Dr. L. A. Parry, the local honorary secretary of the recent annual general meeting of the Association, was presented by the members of the division with a handsome case of cutlery in recognition of his valuable services. The presentation was made by Dr. W. Ainslie Hollis, the President of the Association, who paid a high tribute to the work done by Dr. Parry in organising the arrangements for the meeting. Dr. Parry, who was very warmly received, returned thanks in eloquent terms.

PROPOSED GALTON CELEBRATION.—It is announced by the council of the Eugenics Education Society in the *Eugenics Review* that they have decided to hold each year on Feb. 16th—the anniversary of Sir Francis Galton's birth—a commemorative Galton lecture and dinner, and that the first lecture and dinner will take place on Monday, Feb. 16th next, at the Hotel Cecil, London. Sir Francis Darwin, F.R.S., will deliver the lecture. Further information will be given by the honorary secretary, Galton Celebration Committee, Eugenics Education Society, Kingsway House, Kingsway, W.C.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill announce for publication Volume VIII. of the new edition of Allen's "Commercial Organic Analysis." This volume has been rewritten under the editorship of Mr. W. A. Davis and Mr. S. S. Sadtler. The subjects and authors are as follows: Enzymes, Proteins of Plants, by E. Frankland Armstrong; the Proteins and Albuminoid Substances, Digestion Products of the Proteins, by S. B. Schryver; Proteins of Milk, by L. L. Van Slyke; Milk, by H. Leffmann; Milk Products, by C. Revis and E. R. Bolton; Meat and Meat Products, by W. D. Richardson; Hæmoglobin and its Derivatives, by J. A. Gardner and G. A. Buckmaster; Albuminoids or Scleroproteins, by J. Alexander; Fibroids, by W. P. Dreaper.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Jan. 15th, Sir Francis H. Champneys being in the chair. A letter was considered from the Registrar-General transmitting a copy of a letter from the Superintendent Registrar for the Wolverhampton district with regard to the conduct of a certified midwife in issuing two certificates, one of death and one of stillbirth, in respect of the same child. The Board decided that the case be referred to the Penal Cases Committee. A letter was considered from the secretary of the Bombay Presidency Nursing Association asking the Board to recognise the certificate of the association as a qualification for the entry of a name on the midwives roll, or in the alternative to establish a branch examination of the Board in Bombay. The Board decided that the [illegible] Somerset be thanked for his letter, and that he be informed that the matter has been noted for consideration on the next revision of the rules. A letter was considered from the resident medical officer of the Rochdale Union Infirmary with reference to the difficulty experienced by his pupils with regard to obtaining outside cases in connexion with their training. The Board directed that the resident medical officer of the Rochdale Union Infirmary be informed that the Board regrets that, not being familiar with the local circumstances of the case, it is unable to advise on the matter referred to them.

THE HUNTERIAN SOCIETY.—The next meeting of the Hunterian Society will be held at St. Bartholomew's Hospital in the library at 9 P.M. on Jan. 28th, and will be a clinical and pathological evening. All members of the medical profession are invited to attend.

LIVERPOOL MEDICAL INSTITUTION.—At the annual meeting held on Jan. 15th the following list of office bearers and members of council was adopted:—President: Edward William Hope. Vice-Presidents: Thomas Bushby, W. B. Warrington, R. J. M. Buchanan, and Alexander Stookes. Treasurer: R. J. Hamilton. General Secretary: Frank Hugh Barendt. Secretary of Ordinary Meetings: John Hay. Secretary of Pathological Meetings: D. Moore Alexander. Librarian: Nathan Raw. Editor of the Journal: R. W. MacKenna. Council: W. B. Bennett, R. E. Harcourt, A. W. Riddell, J. A. Howard, M. T. Stack, Robert Jones, J. Hayward Willett, A. C. Ransome, James Huskie, V. Chastel De Boinville, William McAfee, and E. Malcolm Stockdale.

Politachi.—On Jan. 11th, at Glen Lodge, Kersal, Manchester, John Politachi, M.B., Ch.B. Edin.

Reeves.—On Jan. 16th, Henry Albert Reeves, M.R.C.S.

Wise.—On Jan. 8th, at Lindisfarne, Trowbridge, Wiltshire, Nicholas Vincent Wise, L.R.C.S.I., L.K. and Q.C.I., L.M.I., aged 69.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

AMBIGUOUS TITLES.

"What's in a name? That, which we call a rose,
By any other name would smell as sweet"

But when Juliet said this she was referring to the case in which the thing remained constant and the name differed. When the name remained constant and the thing differed, [illegible] a book with the [illegible] ld Know before [illegible] ookery, was the [illegible] few weeks ago, [illegible] mplained to the [illegible] found that the [illegible] which had been [illegible] on the contrary, a very proper one to be in the hands of every young woman Moreover, counsel pointed out that a large number of young women had bought the book, but none of them had complained The art of ambiguous catchy titles seems to have been quite well known to our ancestors. It is said that Louis Antoine Caraccioli (1721—1803) published a book with the ambiguous title of "La Jouissance de Soi Même," and the sale of the book was continual with the libertines, who, however, found nothing but very tedious essays on religion and morality. In the sixth edition the author greatly exulted in his successful contrivance by which means he had punished the vicious curiosities of certain persons, and perhaps had persuaded some, whom otherwise his book might never have reached. On the other hand, as an example of an alluring bait failing to fetch fish, it is recorded that W. J. Mickle, the poet and translator of "The Lusiad" of Camoens, could never fi [illegible] Concubine," written in [illegible] it afterwards (1778) assun [illegible] Martyn."

THE PREVENTION OF VENEREAL DISEASE.

To the Editor of THE LANCET.

SIR,—Some excellent leaflets have been prepared and distributed in Germany by the "Deutsche Gesellschaft zur Bekampfung der Geschlechtskrankheiten." I shall be glad to know if you can inform me of any similar instructions issued in this or other [illegible]

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY.

LECTURE BEFORE THE SOCIETY at 5 P.M.

Surgeon Murray Levick The Experiences of Captain Scott's Northern Party from a Medical Point of View.

SECTION OF ODONTOLOGY (Hon. Secretaries—Robert McKay, F Coleman) at 8 P.M

Discussion:

On Mr. S P Mummery's paper on "The Conservative Treatment of the Pulp"

Casual Communication:

Mr. Leonard Harwood. Case of Congenital Absence of Maxillary Teeth

TUESDAY.

SECTION OF MEDICINE (Hon Secretaries—H Batty Shaw, John Fawcett) at 5 30 P.M.

Discussion:

On Vaccines from the Standpoint of the Physician (opened by Dr. T. J. Horder). Followed by Sir John McFadyean, Dr. Charlton Briscoe, Dr Gillett (Oxford), Dr. Phineas Abraham

The discussion will be continued on Tuesday, Feb 3rd, at 5 P.M., when it will be re-opened by Dr. H D Rolleston.

Mr. G. R. Fox, Beccles; Mr. A. S. Foster, Alcombe; Friedrichshall Mineral Water, Lond.; Dr. Ernest R. W. Frank, Berlin; Mr. T. G. Fenton, Torquay; Dr. W. M. Fairlie, Lond.; Messrs. Fannin and Co., Dublin; Factories, Chief Inspector of, Lond.; Mr. J. W. Fryer, Eastwood; F. R.; Miss F. L. Fuller, Lond.

G.—Messrs. W. Goldsmith and Co., [illegible] Gill, Sheffield; Dr. Edward G. Glover, Midhurst; Mr. Wyndham C. Goodden, Lond.; G. B.; Dr. A. Graham-Stewart, Margate; General Infirmary, Leeds; Messrs. A. H. Grantham and Co., Reading; Garden Cities and Town Planning Association, Lond.; Dr. Douglas J. Guthrie, Edinburgh; Co.-Qr.-Mr.-Sgt. T. Greenwood, Spike Island.

H.—Dr. H. E. Haynes, Brentwood; Mr. J. Smith Hill, Aspatria; Captain A. H. Hayes, R.A.M.C., Havant; Messrs. Hoskins and Sewell, Birmingham; Mr. C. A. Hoefftcke, Lond.; Hove Medical, Turkish, and Swimming Baths, Brighton, Manager of; Mr. E. M. Harvey, Lond.; H. H.; Horton Infirmary, Banbury, Secretary of; Messrs Hatch, Mansfield, and Co., Lond.; Mr. N. Bishop Harman, Lond.; Dr. F. de Havilland Hall, Lond.; Dr. Leopold G. Hill, Lond.

I.—Invernith Sanatorium, Colinsburgh, Secretary of.

J.—Joint Counties Asylum, Carmarthen, Clerk to the; Mr. Edward T. Jones, East Meon; J. R. B. A.; Dr. J. C. Johnson, Lond.; Mr. G. J. Jenkins, Lond.

K.—Messrs. A. Krock and Co., Chicago; Mr. F. E. Kimpton, Lond.; Messrs. H. S. King and Co., Lond.; Mr. J. C. Khambatta, Craghead; King Edward VII.'s Hospital, Cardiff, Secretary of; Kensington Dispensary, Lond., Assistant Secretary of.

L.—Dr. C. E. Lea, Manchester; London Press Exchange, Lond., Manager of; Mr. H. Lett, Lond.; Messrs. Lee and Martin, Birmingham; Dr. M. Lanza, Ottajano; L. F. L.; Liverpool Stanley Hospital, Secretary of; Lady Margaret Hospital, Bromley, Secretary of; Messrs. Longmans, Green, and Co., Lond.; Dr. A. J. Bruce Leckie, Bath; Liverpool Medical Institution, General Secretary of; Local Government Board, Lond., Secretary of.

M.—*Midland Counties Herald*, Birmingham, Secretary of; Messrs. Martin, Clarke, and Co., Lond.; Maltine Manufacturing Co., Lond.; Mr. W. Martindale, Lond.; [illegible] tising Service, Lond.; *Medical Review*, Lond., Manager of; Mr. [illegible] May[illegible] Mess[illegible] Med[illegible] Lon[illegible] R.N., Belfast; Dr. I. B. Muirhead, Lond.; Mr. J. H. Meggy, Lond.; Mr. E. Maynard, Lond.; Mrs. Charles S. Myers, Cambridge; Mr. F. Maxey, Alderney; Medico-Legal Society, Lond.; Dr. H. H. Mills, Lond.; Mr. J. Y. W. MacAlister, Lond., Metropolitan Asylums Board, Lond., Clerk of; Thomas McLean's Galleries, Lond.

N.—North Manchurian Plague Prevention Service, Harbin, Director of; Norfolk and Norwich Hospital, Secretary of; Notts County Council, Mansfield, Clerk to the; Mr. H. Needes, Lond.; Dr. Newell, Margate.

O.—Dr. W. D. O'Kelly, Dublin.

P.—Mr. C. Politachi, Manchester; Dr. F. Pilkington, Lechlade; Messrs. C. Pool and Co., Lond.; Prescot Union, Clerk to the; Mr. J. J. Pickles, Leeds; Dr. J. A. W. Pereira, Exeter; Dr. Eric Pritchard, Lond.

R.—Messrs. Randall Bros., Lond.; The J. D. Riedel Co., Lond.; Messrs. Reynell and Sons, Lond.; Messrs. Reynolds and Branson, Leeds; Messrs. E. J. Reid and Co., Lond.; Royal Society, Lond.; Dr. H. Robinson, Lond.; Royal Isle of Wight County Hospital, Ryde; Royal National Sanatorium for Consumption, Bournemouth, Secretary of; Royal Infirmary, Sunderland, Secretary of; Royal College of Surgeons of England, Secretary of; Dr. R. F. Rand, Frinton-on-Sea; [illegible] ate, [illegible] of; [illegible] Royal Institution of Great Britain, Lond.; Mr. J. M. Rennet, Lond.; Royal Mail Steam Packet Co., Lond.; Registrar-General, Lond.; R. H.; Royal Gwent Hospital, Newport, Secretary of; Royal Meteorological Society, Lond., Secretary of; Royal Academy of Medicine in Ireland, Dublin; Mrs. Aubrey Richardson, Lond.

S.—Mr. E. C. Steinbridge, Lond.; Messrs. Stevens and Sons, Lond.; Saccharin Corporation, Lond.; Dr. G. H. Sherman, Detroit; Dr. Heinrich Stanger, Ulm; Mr. Theodor Steinkopff, Dresden; Southampton Corporation, Clerk to the; Dr. Scrimgeour, Dundee; Messrs. Spiers and Pond, Lond.; Smith's Advertising Agency, Lond.; Southend-on-Sea Corporation, Town Clerk of; *South Wales Argus*, Newport; Mr. Stuart-Low, Lond.; Messrs. G. A Lecture

ON

TUBERCULOSIS AS AN INFECTIVE DISEASE.

Delivered at the Brompton Hospital for Consumption and Diseases of the Chest,

By W. CECIL BOSANQUET, M.D. Oxon., F.R.C.P. Lond.,
PHYSICIAN TO BROMPTON HOSPITAL AND TO THE CHARING CROSS HOSPITAL.

Gentlemen,—In considering the question of tuberculosis as an infective disease it may be well to start by defining the latter term, as it may possibly convey a meaning other than that which it should strictly bear.

Definition of Infective Disease.

An *infective* disease is one which is produced by the entrance into the body of a living organism, animal or vegetable, which then multiplies in the blood or tissues and causes injurious effects. This is not quite the same as an *infectious* disease in the popular sense, which implies one which is directly conveyed from one person to another by contact or association. For example, malaria is an infective disease, due to the action of the well-known plasmodium, but it is not infectious, inasmuch as it can only be conveyed from one individual to another by means of the mosquito, a definite cycle of changes in the parasite taking place within the body of the insect. Sleeping sickness is also an infective, but not an infectious, disease, and others are yellow fever and tick fever. Consequently, when we say that tuberculosis is an infective disease we must not immediately assume that it is directly passed from man to man, though this may be the case. Indeed, this is a point on which opinion has varied from time to time, since it is clear that in the Middle Ages phthisis or tuberculosis of the lungs was looked upon as an infectious disease, but this view was gradually abandoned, to be revived later by Budd, Villemin, and others. At the present time the danger of direct infection seems to have been so impressed on the public by a certain school of writers on sanitary matters that there is danger of sufferers being treated as lepers and shunned as unclean and dangerous, whereas it is fairly clear that the risk of direct communication of tuberculosis is at any rate minimal under good sanitary conditions.

The discovery of the bacillus tuberculosis by Koch in 1882 put the infective nature of the disease on an assured footing, and it might be supposed that now, 30 years afterwards, exact knowledge would be possessed as to the path of infection and the conditions necessary for its occurrence. As a matter of fact, this is not the case, and in view of the common nature of the affection it is really surprising how many serious gaps exist in our knowledge concerning it.

The Bacillus Tuberculosis.

We may first consider what is known of the bacillus and its life conditions, and see what light is thus thrown on the problem of its infective nature. The well-known acid-fast rods encountered in tuberculous lesions grow slowly on laboratory media and are not very resistant to hostile influences, being readily destroyed by sunlight and even by ordinary diffused light and drying. It is generally held that the organism does not form spores, though some writers speak of the granular forms of the bacillus, which are formed by breaking up of the rods, as spores. Besides these—the "granules of Much"—some writers have described a form of the bacillus which does not retain the carbol-fuchsine when treated with acid—a view which would introduce considerable confusion into our accepted ideas if it were generally adopted. The B. tuberculosis is only one of a group of organisms which have this peculiar property of resisting decoloration by acids, owing to the presence of a fatty or waxy coat. The relationships between the members of the group are another subject on which doubt continues to exist. Diseases caused by acid-fast organisms are found in cattle, birds, and cold-blooded animals as well as in human tuberculosis, and the controversy as to the essential unity or diversity of the organisms respectively present is as yet unsettled.

The Bovine Variety of Bacillus.

The important question so far as human infection is concerned is as to the ability of the organism found in cattle to establish itself in man, as it is fairly certain that the avian and reptilian varieties do not constitute a practical source of danger. On the answer to this question depends our recognition of a very important source of infection, and the absence of certainty on this point constitutes, perhaps, one of the most serious of all the gaps in our knowledge of the disease. Tuberculosis is very common among cattle, and the bacilli are often present in the milk; hence, if infection can be conveyed to mankind by their means it is possible that a large proportion of human tuberculosis is due to consumption of the milk of tuberculous cattle. Consequently, a large amount of attention has been devoted to the feasibility of infection from bovine sources.

Direct experiment as to transmission of bovine bacilli to man is, of course, impossible, and we are compelled to rely on evidence as to the strain of organisms found in human patients and as to the probable point of entry into the body. Identification of the bovine variety or species depends partly on its morphological and cultural characteristics, and partly on its effect when injected into rabbits in which it produces rapid general tuberculosis, whereas the human form causes only a chronic lesion. This method of examination presumes that the bovine bacilli remain constant in form and virulence when transferred to another host, and it is noteworthy that Eber[1] states that he has been successful in causing alteration both in form and virulence by passing human bacilli through guinea-pigs and then inoculating cattle; in these latter animals infection resulted, and the organisms were found to have assumed the bovine character. If this be confirmed it is likely that bovine bacilli in human beings may revert to or develop into the human type. The British Commission,[2] however, maintains that the several varieties are practically stable, and this is the view of the majority of observers at the present time.

As to the liability of children to become infected with bacilli from a bovine source, the Commissioners speak very definitely. There is, they say, "no doubt that a considerable proportion of the tuberculosis affecting children is of bovine origin," or that "primary abdominal tuberculosis, as well as tuberculosis of the cervical glands, is commonly due to ingestion of tuberculous infective material." Again, the potency of tuberculous cow's milk in causing the disease is, in their view, "clearly and butchers have directly infected themselves in the dissection of tuberculous cattle, the resulting local lesion and lymphangitis leading in some instances to a generalised condition, terminating in pulmonary tuberculosis.

CAUSE OF DISEASE IN LATER LIFE.

Having arrived at the conclusion that infection with tuberculosis is very widespread, and that it takes place with great frequency in early childhood, we are met by the question as to the cause of the outbreak of the disease at later periods of life; for it need not be said that of the children who are tested and found to react to a tuberculin test only a small number are suffering from or rapidly develop actual disease.

Two possibilities suggest themselves: either that the bacilli which enter the body in childhood remain in a latent condition for a considerable period of time, until some evil influence leads to a reduction in the resistance of the host; or that adult tuberculosis is practically unconnected with the infantile contamination and results from renewed external infection. Von Behring at one time adopted the view that infection during childhood with bovine bacilli and recrudescence in later life was the usual sequence; and though at present the tendency is to refer the infection of children mainly to human sources, the "recrudescence" theory serves to explain the large proportion of cases in which no source of immediate infection can be traced. The two views are not, of course, mutually exclusive, and it is quite possible, even probable, that both may be true. At present, however, we have to recognise in this uncertainty another gap in our knowledge of tuberculosis.

Whether, then, the disease is relit or reinoculated it is clear that there are special causes at work which render some persons liable to contract tuberculosis, while others escape. These are the so-called "predisposing causes" of the disease. It is very generally admitted that some families suffer more than others from this affection, and it seems probable that there is some inherited peculiarity of constitution which induces this susceptibility. We call this a hereditary weakness of resistance to the bacilli. Instances of such strains of the human stock are within the experience of us all. Among my out-patients at this hospital I had one woman who had lost eight brothers and sisters from the disease; another had lost five brothers and sisters and one parent, and so forth. Members of these delicate families may succumb to tuberculosis, although they do not live under the same roof, but are scattered over the country, so that their special liability can hardly be attributed to direct infection from the same source, unless they are supposed all to contract the disease in infancy when they are together. Nevertheless, a family history of tuberculosis is only obtainable in a minority of all cases. Dr. Shrubsall[9] found that out of 1045 patients in this hospital 410 only had any tuberculous relative (39·2 per cent.); of these 230 had one or both parents affected, with or without other relatives. It is thus apparent that undue importance is often attached to the hereditary taint, and some authors even deny its existence altogether—for example, Calmette. The prognosis does not seem to be markedly worse in the hereditary than in the other cases.

THE INCIDENCE OF TUBERCULOSIS.

Doubts have been expressed as to any increased incidence of tuberculosis on particular races, but there seems definite evidence that the Jewish stock is rather less liable to infection than are the European races, while Celts and negroes suffer severely. Among Europeans it is said that the red-haired type is specially prone to tubercle. No age is exempt, but the young are specially liable to infection, the greatest mortality occurring in children under 5, and they suffer from the acute form of the disease and from affections of bones and joints especially. Some curious observations have been recorded in the Registrar-General's report for this country as to incidence on the two sexes, for whereas tuberculosis used to affect females most, now males suffer more. It is difficult to suggest any valid explanation of this phenomenon. Dwellers in towns, as already noted, fall victims to the disease with much greater frequency than countrymen, the incidence of tuberculosis rising markedly with every increase in density of population.

Careful observations have been made which show a definite connexion between defective housing conditions and the tuberculosis rate, back-to-back houses being especially often centres of the infection, while a direct parallelism can be traced between the existence of conditions of overcrowding and tuberculosis. Thus Henschen[13] investigated the question in Stockholm, and found that the incidence of tubercle in some of the poorer quarters was directly related to the number of persons per room, with the single exception of a district in the oldest part of the town where the rooms were so small that it was impossible for many persons to squeeze into each of them. This connexion between tuberculosis and defective housing has now been recognised by a multitude of observers and may be regarded as firmly established. It agrees with what is known as to the characteristics of the bacillus as previously noted. Dr. Clement Dukes says, "Tuberculosis is more a house disease than an infectious disease."

Similarly, a parallel can be drawn between the poverty of the inhabitants of a district and their liability to consumption. Thus in Hamburg the death-rate per 10,000 living was 10 among persons with an income of over 3500 marks (or say £175) per annum, 39 in those with incomes between 900 and 1200 marks, and 60 among those with 900 marks or under. Thus we find in the case of tuberculosis the verification of the saying of Sir J. Simon that "poverty in its severer forms is among the worst of sanitary evils."

Occupations and other Predisposing Causes.

Certain occupations seem to render those engaged in them more susceptible to tuberculosis. In this country the highest death-rate is in tin-miners, who are followed by filemakers, while lead- and copper-miners also suffer severely, but coal-miners little. Innkeepers and costermongers form other fatal trades. Artisans as a class escape fairly lightly, while farmers are the healthiest of all in respect of this infection.

The high rate among innkeepers is connected with the question of the abuse of alcohol as a predisposing cause of tuberculosis—one to which diverse answers have been given. On the one hand, the experiments which have been made on animals, by giving them alcohol and estimating their liability to contract tuberculosis and the rapidity of the disease when established in them as compared with that in normal animals, can hardly be used as a weighty argument for a similar effect on mankind. Henschen, who points out that the tuberculous death-rate in

Sweden shows a parallelism with the consumption of alcohol, is yet inclined to believe that the drug has little direct influence on the origin of this infection. He draws attention to the fact that alcoholics are usually reduced by their excess to poverty, and that their surroundings are unsatisfactory. He is supported in attaching little weight to intemperance in itself by the statistics of the Phipps Institute in the United States. On the other hand, Brouardel held the opinion that alcohol is the most powerful factor in the spread of tuberculosis; and it appears to be established that the abuse of alcohol may diminish the amount of protective substances present in the blood. Further, everyday observation, if we may so call it, tends to create a belief in the action of this substance in predisposing to consumption and other forms of [illegible] of tuberculous peri- [illegible] om cirrhosis of the [illegible] re definite information we may remain—if not, as Disraeli said, "on the side of the angels," at least on the side of the teetotalers in this particular respect.

The action of other diseases in predisposing to tuberculosis is well known. As examples we may note the frequency of an outbreak of the disease in children after measles or whooping-cough and the liability of diabetic subjects to succumb to rapid pulmonary tuberculosis. Mediterranean fever and congenital defects of the heart may also be mentioned in this connexion. Some authors have attributed the occurrence of tuberculosis of the lungs to such anatomical peculiarities as a constriction of the upper thoracic aperture or congenital smallness of the heart. Local injury in the form of sprains and bruises seems to lead in some instances to tuberculosis of joints and bones.

FORMS OF THE DISEASE.

Time does not admit of a lengthy account of the nature of the disturbances brought about in the body by the tubercle bacillus. It is necessary, however, to point out that the disease takes two main forms—one the acute generalised infection, and the other the chronic destructive variety seen in pulmonary, renal, and other local tuberculoses.

Acute general miliary tuberculosis is met with most often in children, and the bacilli are carried by the blood stream and deposited in practically all the organs of the body, where they give rise to the familiar small nodules, histologically consisting of giant, epithelioid, and small round cells. The giant and epithelioid cells are seemingly derived from the lining cells of the lymphatic channels in which the bacilli settle and multiply. The disease is characterised by high irregular fever and signs of general toxæmia, diagnosis from enteric fever being often difficult; and the condition points to a rapid multiplication of the organisms and vigorous manufacture of toxins, the host having scarcely any power of resistance against the invasion.

In the chronic form, on the other hand, the bacilli settle in some local focus and the disease extends by continuity of tissue—that is to say, by way of the minute lymphatic spaces and channels—producing a gradual destruction of the organ attacked, but often failing to establish itself in any other. This failure is apparently not due to the fact that the bacilli are imprisoned in the tissue at the original seat of infection, as many observers have noted that in pulmonary tuberculosis bacilli can be found in the blood stream. Inability to extend to other parts seems to be due to the existence of some general immunity against attack. In the final stage of the disease, indeed, when the resistance of the host is worn out, an extension of miliary tubercles may occur to more distant parts of the affected organ and also to other parts of the body. Thus we may see the termination of a case of consumption brought about by an acute miliary tuberculosis of the remaining portions of lung tissue or by tuberculous meningitis.

THE TOXINS AND MECHANISM OF RESISTANCE.

As to the nature of the poisons formed by the tubercle bacillus little certain knowledge seems to exist. Three varieties have been described—fatty bodies from the covering membrane of the bacilli, soluble products of their activity, and the actual proteins representing the living substance of the organisms. Among the definite effects due to one or other of these may be noted the production of fever—a general reaction—and the necrosing property which results in caseation. Whether a special poison is associated with the tendency to sweat is not clear. Piéry[14] has asserted that tubercle bacilli are eliminated with the sweat.

If little is known of the toxins at work, it is not surprising that we are equally uncertain as to the mechanism of resistance. No definite antitoxin *analogous to* [illegible] has *been* identified. Of [illegible] occurs in the case of c [illegible] known, though some writers regard the granular appearance of the bacilli seen in certain cases as evidence of commencing lysis. Phagocytosis certainly occurs, and in pleural and pericardial effusions the leucocytes can be seen loaded with bacilli, while the opsonising action of the serum has been sufficiently proved; but it is not by any means clear that phagocytosis is an important factor in immunity to tubercle. We are left with the possibilities either of some substance in the serum which inhibits the growth of the organisms, though it does not actively destroy them, or of an increased power acquired by the tissue cells of resisting the destructive action of the toxins. Anatomically, arrested tuberculosis is characterised by areas of dense fibrous tissue in the centre of which there may remain living bacilli. That some antibody is formed in the infection seems sufficiently proved by the phenomenon of complement fixation (analogous to the Wassermann test for syphilis) which is pretty constantly present in tuberculous patients. A short experience of this reaction as a clinical test for tuberculosis—too short to enable any very certain statement to be made—suggests that it is at least as trustworthy for diagnostic purposes as the agglutination test for enteric fever associated with the name of Widal. Some actual agglutination of tubercle bacilli may be effected by the serum of tuberculous patients.

The possibility of producing an increase of resistance in animals by vaccines of tubercle bacilli was for a long time in doubt, attempts to produce attenuated strains of the organisms usually proving abortive. Positive results have been, however, reported from time to time, some of the most recent being those of Webb and Williams[15] in America, who were actually encouraged to try inoculation of living bacilli into children of tuberculous parents as a prophylactic against infection. The doses used were infinitesimal, starting with one bacillus and rising to only 150, but these observers claimed that there resulted a gain of weight and general improvement in health. Some degree of immunity is apparently produced in cattle by injection of tubercle bacilli derived from human sources, second twenty-four hours of an attack, 152 in all, 6 died, a percentage of 3·9; whereas of those in whom operation was postponed until the third day of the attack, 115 in all, 10 died, a percentage of 8·7. I do not think that any deductions can be drawn from the death-rate of the cases operated upon from the fourth to the ninth days, as the numbers are so small. But attention may be drawn to the fact that of the 58 patients operated upon on the tenth day or later only 1 died. If Table B is examined for details of these cases, it will be seen that 40 were cases of abscess and in 14 the inflammation was limited to the appendix—in other words, that in 54 cases the condition was well localised, consequently there was much less danger in operating upon them than in cases which were not so localised.

TABLE B.—*Showing the Mortality of Operation on the Different Days of the Attack.*

Day of attack.	Inflamed.		Local peritonitis.		Abscess.		General peritonitis.		Total.		Mortality per cent.
	Recovered.	Died.	Recovered.	Died.	Recovered.	Died.	Recovered.	Died.	Recovered.	Died.	
First day	99	1	35	0	13	0	13	1	160	2	1·2
Second day... ...	62	0	39	1	25	1	20	4	146	6	3·9
Third day	40	0	10	3	43	2	12	5	105	10	8·7
Fourth day	22	0	10	1	10	0	6	1	48	2	4
Fifth day	12	0	3	0	17	0	3	1	35	1	2·8
Sixth day	5	0	4	0	11	0	1	0	21	0	0
Seventh day ...	9	0	3	0	23	1	6	2	41	3	6·8
Eighth day	4	0	1	0	5	0	0	0	10	0	0
Ninth day	2	0	1	0	5	2	1	2	9	4	30·7
Tenth day or later	14	0	3	1	40	0	0	0	57	1	1·7
Day not stated ...	14	0	8	0	12	1	2	0	36	1	2·7
Total	283	1	117	6	204	7	64	16	668	30	4·3

These statistics illustrate the value of early operation, during the first twenty-four hours of the attack if possible, and the cases are sufficiently numerous to justify the statement that operation during the first twenty-four hours is attended with extremely little risk; operation during the second day with considerably more risk, though it is still small; but if operation is postponed until the third day the prognosis is much more serious.

Some may argue that the results obtained in the operations on the tenth day or later are strongly in favour of postponing operation. The reply, of course, is that it is generally impossible to tell in which cases the inflammatory process will become localised and operation may be deferred with safety. I would once more point to the total mortality of 3·2 per cent. in this series, compared with the total mortality of 17·2 per cent. in the series published in 1905, when operation was very rarely performed in the first stages of the attack, but was postponed as long as possible, in order to allow the attack to subside, or failing this, to allow the inflammation to become localised. The earlier statistics illustrate the results of postponing operation; the present ones the result of operating early. If all cases could be left with safety until the tenth day the general mortality would be still lower than it is; but unfortunately they cannot, and it is therefore our duty to remove the appendix at a time when the risk is reduced to a minimum—that is, during the first twenty-four hours—a procedure which offers the prospect of a mortality of only 1·2 per cent.

Complications of Acute Appendicitis.

Unfortunately, it is by no means rare for the patient's convalescence to be delayed by certain complications which may arise during the attack. Thus we find that out of 698 patients operated upon during the acute stage, in 83—that is, 11·9 per cent.—various complications arose. Among them were 25 cases of fæcal fistula, 22 cases of secondary abscess, 17 pulmonary complications, and 12 cases of intestinal obstruction. Three patients had more than one complication; for example, of two of the cases of pleural effusion, one was associated with a subdiaphragmatic abscess and the other with bronchopneumonia, and the patient with empyema also had a subdiaphragmatic abscess.

That 4·9 per cent. of all patients operated upon during an attack of appendicitis, or 1 in 8, should suffer from complications is very unsatisfactory, but even so, it is a great improvement on former results. In the 1905 series, out of 636 cases of acute appendicitis, 146, or 22·9 per cent., had complications. The percentage has therefore been reduced from 22·9 to 11·9 per cent. The explanation of this reduction is easily found; there can be no doubt that it is due to operating early instead of postponing it until the patient has developed an abscess or general peritonitis. For on investigating the 83 cases in which complications arose, we find that in all but six there was an abscess or peritonitis, general or local, in the great majority an abscess or general peritonitis. Of the six cases in which the inflammation remained localised to the appendix, one was a case of intestinal obstruction in which the appendix itself formed the obstructing band, and probably became gangrenous in consequence of the cutting off its blood supply by the stretching of the appendix and its mesentery.

TABLE C.—*Showing the Complications which Occurred.*

—	1905 series.		Present series.	
Total number of cases operated upon during the attack	636		698	
Secondary abscess	16		22	
Subdiaphragmatic abscess	6		4	
Fæcal fistula	49		25	
Thrombosis	12		4	
Pulmonary complications—	45		17	
Pulmonary embolism		1		0
Empyema		7		1
Pleural effusion		14		4
Pleurisy without effusion		2		0
Bronchopneumonia		17		7
Lobar pneumonia		0		2
Bronchitis		4		3
Intestinal obstruction	10		12	
Pylephlebitis	4		2	
Parotitis	4		0	
Total number of complications	146		86	

Note.—One of the patients with pleural effusion also had a subdiaphragmatic abscess, and another had bronchopneumonia. The patient with empyema also had a subdiaphragmatic abscess.

Secondary abscess.—Secondary abscesses form a large proportion of the complications, for as will be seen on reference to Table C, a secondary abscess developed in no less than 22 of the 83 patients apart from the four patients who had a subdiaphragmatic abscess. The majority occurred in the pelvis in the rectovesical pouch, as a natural consequence of the routine adoption of the valuable Fowler's position, which causes all free fluid in the peritoneal cavity to gravitate to the pelvis. But the number of these cases of secondary abscess is, I think, unnecessarily large; indeed, including the cases of subdiaphragmatic abscess it is greater than the number of secondary abscesses in the 1905 series, in which there were only 22. The frequency of this complication is due, I think, to inadequate drainage. A few years ago there was a tendency to leave drainage tubes in too long; more recently the pendulum had swung to the opposite extreme, and drainage was not continued long enough, and, indeed, in some instances not employed where it was necessary. Fortunately, the prognosis is good—none of the cases of secondary abscess proved fatal.

Subdiaphragmatic abscess.—A subdiaphragmatic abscess occurred four times. In one case it was associated with clear fluid in the right pleura, and in another case with a right empyema. All four abscesses occurred in old-standing cases; in two there was general peritonitis, and operation was not performed until the fifth and sixth days of the attack; in two there was an abscess. All four cases recovered. These results are unusually good. Hoffmann quotes Körte, who collected 60 cases, with a mortality of 33·3 per cent. Barnard collected 76 cases, 40 lived and 36 died, a mortality of 47·4 per cent. Twelve of these were not operated upon and they all died. Of the 64 who underwent operation 24 died, a mortality of 37·5 per cent. But of the 21 consecutive cases operated upon by Barnard himself only 17·7 per cent. died, a proportion which is a truer representation of the mortality of subdiaphragmatic abscess at the present day. We must regard a subdiaphragmatic abscess as a serious complication. For although the four cases mentioned above all recovered, the number is too small to justify any deductions as to the mortality of this condition; nevertheless, the fact that they did all recover is encouraging.

Fæcal fistula.—A fæcal fistula is far more likely to occur in a patient who is operated upon late in an attack than in one who has been operated upon within the first 48 hours. It may result from any of the following causes: 1. Direct extension of the gangrenous process from the appendix to the cæcum or ileum. 2. Imperfect occlusion of the appendix stump. This may occur in cases in which only part of the appendix has been removed, as the proximal part could not be discovered, or it may occur in those cases in which an invaginating purse-string suture placed in the wall of the cæcum round the insertion of the appendix has either cut through the inflamed and œdematous tissue or given way. 3. It may be due to actual tearing of the intestine at the time of operation. 4. It may be due to patches already ulcerated and eroded, which, when freed from the adhesions which support them, perforate. 5. The pressure of a drainage tube on the intestine. In cases of prolonged suppuration, this pressure, combined with sepsis, may give rise to ulceration of the intestine, with subsequent formation of a fæcal fistula. Most of these fistulæ can be avoided by early operation; the following case may be given as an example.

About two years ago I operated upon a boy aged 18 years, 36 hours after the onset of the attack. The appendix was gangrenous and continuous with it was a gangrenous patch on the cæcum of the size of a five-shilling piece. The appendix was removed, the gangrenous part of the cæcum invaginated, and the patient made a rapid and uninterrupted recovery. If an early operation had not been undertaken a fæcal fistula would have been inevitable.

Of the 25 cases of fæcal fistula there were only four in which the operation was performed within the first 48 hours. In the great majority of cases the fæcal fistula followed an old-standing abscess. In the present series of cases fæcal fistula occurred 25 times in 698 acute cases—that is, 3·6 per cent.—a reduction of about 50 per cent. on the incidence of fæcal fistula in the cases of 1905, for among them out of 637 patients who were operated upon for acute appendicitis, 49—that is, 7·7 per cent.—had fæcal fistula.

Thrombosis.—This is another complication which is met with less frequently than formerly. Thrombosis of the femoral veins occurred four times, twice on the right side and twice on the left, compared with 12 times in the 1905 series. It is more common for the left femoral vein to be thrombosed than for the right one, though not in as great a proportion as occurred in these 12 cases—namely, 11 on the left to 1 on the right.

In the present series of cases the first was a boy with a retrocæcal abscess who had been ill for five days before his admission to the hospital; the second case, a man aged 45, had an abscess and had been ill for ten days; in the third case, a man aged 53, there was no abscess, but the operation was a difficult one, and there were many adhesions. The fourth patient was a man aged 65, who had general peritonitis with a gangrenous appendix, and who had only been ill for a day and a half. In the latter case there is little doubt that the age of the patient and his feeble circulation predisposed to thrombosis. All four patients recovered.

Pulmonary embolism.—In connexion with thrombosis we must consider the extremely important condition of pulmonary embolism. There was no case of pulmonary embolism in the present series, but in 1905 there was one case, which proved fatal. In 4000 cases of appendicitis Hoffmann reported 39 cases of thrombosis of the femoral veins, and no less than 22 of these gave rise to pulmonary embolism, 18 of these 22 cases proving fatal. McWilliams in 685 acute cases found four cases of pulmonary embolism, of whom three died, on the third, ninth, and tenth days. If we take these two reports together, we see that out of 26 cases 21 died, a mortality of 80·8 per cent.

Garré and Quincke allude to the varying mortality of pulmonary embolism in the statistics of different authors. They quote the following:—

Lotheissen	found	52	deaths out of	61	cases	= 83·3%
Albanus	,,	10	,, ,,	23	,,	= 43·5%
Gebele	,,	11	,, ,,	14	,,	= 79·0%
Wyder	,,	8	,, ,,	12	,,	= 66·0%

The difference is probably due to the inclusion of slight cases by some authors, while others only included cases in which the symptoms were pronounced and severe.

Pulmonary embolism is, perhaps, the greatest tragedy of surgery, and any treatment which is likely to prevent this calamity should receive most careful attention. Hoffmann has obtained remarkable results by making the patient stand up out of bed, even if only for a minute, the day after operation, and this is repeated on subsequent days. If it is quite impossible for the patient to stand, passive and active movements of the lower extremities are instituted, and, later, massage. His statistics embrace all cases up to the year 1912, and this treatment was begun in the year 1908. After the introduction of this treatment there were only 3 cases of thrombosis and emboli, compared with 36 in the previous years, and none of these 3 had been made to get out of bed the day after operation. This is most suggestive, and the treatment is worthy of very careful consideration.

The mortality of severe cases of pulmonary embolism appears to be about 75 per cent., but, as was pointed out by Sir R. Douglas Powell, in all probability many of the cases of bronchopneumonia, empyema, and pleurisy which arise as complications of appendicitis are really embolic in origin. Fortunately, we can say that at the present time, with modern methods of treatment, fatal pulmonary embolism is an extremely rare complication of appendicitis.

In four cases the pulmonary artery has been opened and the clot removed by Trendelenburg's operation. The most successful case was a woman operated upon by Krüger; she lived for five days and a quarter after the operation, and died from purulent pleurisy.

Other pulmonary complications.—Pulmonary affections form a large proportion of the total number of the complications; in the 1905 series they formed 45 out of a total of 146, a proportion of nearly one third, and in the present series 17 out of a total of 86. Reference to Table C will show the relative frequency of the different conditions, bronchopneumonia heading the list, and pleural effusion coming second.

Empyema only occurred once, and then was in association with a subdiaphragmatic abscess. In the 1905 series there were seven cases of empyema; they all appeared to be the result of direct extension of the inflammatory process from below the diaphragm to the pleural cavity. A left-sided empyema occurred once in connexion with a left subdiaphragmatic abscess.

Pleural effusion occurred in four cases—in one the patient had been ill three weeks and had a subdiaphragmatic abscess. The second patient was operated upon for general peritonitis on the third day of the attack, and developed double pleurisy and bronchopneumonia. Both of the other two patients had local peritonitis, and the fluid was on the right side of the chest.

In the remaining cases of bronchopneumonia and lobar pneumonia there was an abscess or peritonitis in nine. Bronchopneumonia developed in one case of acute appendicitis in which the inflammation was limited to the appendix, and in another similar case, in which there were adhesions and free fluid in the peritoneal cavity, the patient had right lobar pneumonia.

A patient aged 64, who had a perforated appendix and was operated upon four days after the beginning of the attack, died from bronchitis and heart failure.

These results are striking evidence of the relation between late operation and pulmonary complications, and indicate the prophylactic value of operation during the first 24 hours of the attack. This is borne out by the 1905 series. *There was an* abscess or general peritonitis in 13 of the 14 cases of pleurisy with effusion, and in 15 of the 17 cases of bronchopneumonia—the remaining 2 cases were considered to be examples of ether pneumonia. The 7 cases of empyema have already been referred to; they were all associated with an abscess or general peritonitis.

Intestinal obstruction.—Intestinal obstruction is a grave and not uncommon complication of appendicitis. In the 1905 series of cases there were 10 cases of intestinal obstruction, giving a percentage of 1 for all cases, and 1·5 per cent. if only the cases of acute appendicitis are included. In 9 there was definite mechanical obstruction by bands, adhesions, &c. Only 1 case of ileus is recorded, though there were probably more. Six of the patients died and 4 recovered. In the 1912 statistics I found 12 cases of intestinal obstruction—that is, 1·2 per cent. of all cases, or 1·7 per cent. of the acute cases. The obstruction may be either paralytic or mechanical. In the paralytic variety or ileus there is paralysis of the intestine with resulting symptoms of intestinal obstruction. In my present series there were five examples of this condition, and four of them died. In its milder forms it is commonly met with, and therefore it is possible to assume that there were other cases in which ileus was present to a slight degree, but no mention has been made of it. When ileus occurs in an attack of appendicitis it is always of grave prognosis, but less so when it occurs early in an attack than later. In the former condition, particularly when it is present before operation, it is often possible to overcome it by appropriate treatment, but when it occurs in the later stages the prognosis is very grave.

Mechanical obstruction occurred in seven cases. It may be due to the presence of adhesions producing a kink in a piece of intestine or adhesions may take the form of a band, which may form a loop round a piece of intestine and so ensnare it, or a loop of intestine may pass underneath it and become strangulated in that way. Lastly, the appendix itself is not very uncommonly the immediate cause of intestinal obstruction. I recently operated upon a patient in whom the tip of the appendix was adherent to the root of the mesentery; it had formed a loop, and through this loop a piece of intestine had passed and was tightly gripped. Not only was the intestine gangrenous, but also the appendix itself. When the appendix forms the constricting band the prognosis becomes rather more serious, as not infrequently the stretching of the appendix has cut off its blood-supply and gangrene has followed, with resulting general peritonitis. In these cases the primary condition appears to be that of intestinal obstruction, with secondary gangrene of the appendix.

Ruge found 44 cases of intestinal obstruction in 2385 cases of appendicitis, a proportion of 1·8 per cent., which is not very far from the proportion of 1·2 per cent. in my cases. Among these 44 there were 14 cases of ileus, 7 of whom recovered and 7 died. Of the other cases the appendix itself formed the constricting band in no less than 6; of these only 2 recovered and 4 died.

The frequency with which intestinal obstruction occurs, as is the case with nearly all the other complications of appendicitis, depends largely on the time at which the primary operation is performed. It is interesting to note that in all of my 12 cases either an abscess or general peritonitis existed. None of these cases had been known as early operation, that is, within the first 24 hours, or even the first 48 hours.

In discussing intestinal obstruction due to appendicitis one must bear in mind the possibility *of an attack of appendicitis leaving behind it bands* and adhesions, which may cause intestinal obstruction at a later date. The prognosis is grave. Of the 10 cases in the 1905 series 4 recovered and 6 died; in the present series 6 recovered and 6 died; while of Ruge's cases 23 recovered and 21 died; a total of 33 recoveries and 33 deaths, giving the high mortality of 50 per cent.

Jaundice.—Speaking generally, when jaundice complicates an attack of appendicitis the prognosis is grave. Hoffmann has recorded 11 cases; in nearly all of them there was acute perforative appendicitis, in several diffuse peritonitis, or extensive abscesses. He regards jaundice as a sign of very severe illness, especially if it appears early in the attack. Reichel thinks that jaundice may arise from the spreading of infectious material, and therefore advises that in the case of an abscess one should be content with opening it only, and nothing more, when the disease has existed 48 hours. Eight of his 18 patients who had jaundice recovered, a mortality of 55·55 per cent., but of Aldehoff's 14 cases 11 recovered and only 3 died. It may be due to various causes, and may appear at various stages of the illness. The following are the principal causes: (1) Simple catarrhal jaundice; (2) toxæmia; (3) direct extension of the inflammation from the appendix to the gall-bladder and biliary ducts; (4) pylephlebitis; and (5) the so-called delayed chloroform poisoning.

1. *Simple catarrhal jaundice.*—I recently saw a case of this sort in which the patient's illness began with vomiting; catarrhal jaundice shortly followed, and on the next day pain began in the right iliac fossa. Operation was performed within 36 hours, and an acutely inflamed appendix removed. The jaundice followed the usual course of catarrhal jaundice and subsided in the ordinary way after a brief period in which the stools were clay-coloured, the urine contained large quantities of bile pigment, and the skin and sclerotics were deeply tinged with yellow. This is the least serious form, and may be met with in varying degrees; in some cases there is merely a slight and evanescent tingeing of the sclerotics, but in others, as in the case just described, the patient may pass through a typical attack of catarrhal jaundice.

2. *Toxæmia.*—The second class consists of cases in which the jaundice appears to be the result of toxæmia. A good example of this has been described by Holländer. The patient had well-marked jaundice with an appendix abscess. The abscess was opened and drained and a gangrenous appendix removed. The jaundice disappeared within two or three days. In consequence of his experience in this case, Holländer suggests that when jaundice is present in cases of acute appendicitis it indicates that the appendix is gangrenous. There are also mild cases in which the jaundice appears in the early stages of the attack, and passes off shortly after operation; they probably belong to this second class.

3. In the third class are placed cases in which there is a direct extension of inflammation of the appendix to the gall-bladder, and numerous adhesions are found about the gall-bladder.

4. *Pylephlebitis.*—The fourth class is composed of cases which are still more serious. I refer to those cases in which jaundice is a result of portal pyæmia or acute pylephlebitis. These cases are, fortunately, rare. In the 1000 cases which I collected in 1905 there were 4 cases of pylephlebitis, all of which died. In the present series *there were 2 cases, one of which was due to* actinomycosis. It is, however, important to remember that jaundice is not always present in these cases. In neither of the two cases reported by Bidwell, one of which recovered, was there jaundice. The diagnosis of the condition is generally easy. The usual history is that of an attack of acute appendicitis, the formation of an abscess, and, after a varying interval, the onset of rigors, and a few days later the appearance of jaundice. A little later still the liver may enlarge and become tender. It is interesting to note, however, that this is by no means invariably the sequence of events. I remember a patient who was, some years ago, in the London Hospital under my care with jaundice, enlargement of the liver, and tenderness in the region of the gall-bladder. There was *a history of an acute attack* of pain on the right side of the abdomen three weeks previously. The temperature was raised. A diagnosis was made of acute cholangitis secondary to gall-stones, but operation proved that the patient had pylephlebitis with a small retrocæcal abscess and a perforated appendix. I have been rather struck in the few cases which I have come across by the comparatively mild local signs of appendicitis; but this cannot be taken as the rule, for in 7 cases reported by Hoffmann, 2 followed acute appendicitis, 3 after incising an abscess, and 2 after operation for diffuse peritonitis. Sasse, however, reports 2 cases in which the appendicitis was of such a mild type that the patients were not confined to bed; but about ten days after the beginning of the attack they developed symptoms of pylephlebitis and died a few days later. The gravity of the condition lies in the fact that as a rule the liver is riddled with small abscesses, and so is beyond surgical treatment. In Hoffmann's 7 cases, in only 2 was there an abscess sufficiently large to be incised; one of these recovered, but the other patient died. In my own experience I have had 2 cases which recovered, one of them a patient with a large abscess, which was drained, and the other a case of considerable interest, in which, on exposing the liver, I found numerous small abscesses the size of a pea or less; the staphylococcus pyogenes aureus was found in pure culture, a vaccine was prepared and given, and the patient made a good recovery. While the prognosis in cases of pylephlebitis is necessarily grave, it is not hopeless, and an exploratory operation should always be performed, and the condition found dealt with by drainage, where possible, otherwise by vaccines. It also goes without saying that in these cases the primary focus of the disease—namely, the appendix—should always be removed. With regard to treatment, Wilms has published a very remarkable case in which he ligatured the efferent veins leading from the appendix. This patient had had five rigors, but after the veins were ligatured the rigors ceased, and the patient made a good recovery without gangrene of the intestine, or any interference with peristalsis. Sprengel attempted to carry out a similar operation in a patient upon whom he had operated and removed a gangrenous appendix 36 hours after the beginning of the attack. Nine days after removal of the appendix the patient had a rigor, and two or three

1905, and 2 cases of pylephlebitis as opposed to 4. Further, with very few exceptions, all the complications in the present series occurred in patients who, at the time of operation, were either suffering from abscess or from general peritonitis. Another point in favour of early operation, apart from the prevention of such grave conditions as the formation of an abscess or general peritonitis, is the fact that in the great majority of cases it is possible to close the wound and obtain union by first intention.

Lastly, another point—and a point of considerable importance in the prognosis—is the fact that appendicitis is essentially a disease where relapse is the rule and where freedom from recurrence is the exception. And the only cure is treatment by operation. Medical treatment may be successful in tiding the patient over an attack, but the probability that further attacks will supervene is very great. Of 233 cases collected by Karrenstein 50·2 per cent. had further attacks—60 per cent. in the first year, 20 per cent. in the second, and 20 per cent. subsequently. Of 1933 cases Kümmell found that 989, or 51·1 per cent., had had previous attacks. When operation is performed in the early stages of an attack the appendix can always be removed, and thus the possibility of further attacks is obviated.

Lower Berkeley-street, W.

TRAUMA IN RELATION TO CERTAIN ASPECTS OF NERVOUS DISEASE.[1]

BY C. M. HINDS HOWELL, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN, GREAT NORTHERN CENTRAL HOSPITAL; ASSISTANT PHYSICIAN, NATIONAL HOSPITAL FOR PARALYSED AND EPILEPTIC, QUEEN-SQUARE; AND MEDICAL REGISTRAR, ST BARTHOLOMEW'S HOSPITAL.

THE relation of trauma to disease has always been a matter of very considerable interest, both from a practical as well as a theoretical point of view. It is unnecessary for me to emphasise the difficulties which often arise in deciding what part trauma has played in the production of certain morbid conditions. On the other hand, the relationship in many cases is quite clear. Both the importance of the question and the difficulties connected with it have materially increased during recent years, owing to legislation which has been introduced in connexion with the subject.

Probably in no other department of medicine is the influence of trauma in the production of incapacity more pronounced, or harder to estimate fairly, than in its relation to the nervous system. The difficulty arises not so much in connexion with organic disease, which may have been caused by trauma, as in connexion with various functional conditions of post-traumatic origin. Many of these are of a purely subjective character, and human nature being what it is, the tendency to exaggeration has ample opportunity for appearing. This tendency is, of course, exhibited more particularly by individuals of a neurotic disposition, whose nervous system is especially liable to disturbance as the result of accident. In these cases the trauma is as much psychical as physical. It is the duty of the physician to form an estimate of the extent to which the symptoms complained of may fairly be attributed to the injury received, and it is in this respect that so much difficulty arises.

As the relationship of trauma to nervous disease is a very wide one, I propose to select certain aspects only for consideration. As a result of trauma both organic and functional disorders occur in the nervous system. The former bear, as a rule, a direct focal relationship to the injury which caused them, whilst the latter do not. For instance, cerebral symptoms of a functional character may follow an injury to the back, or, again, hysterical paraplegia may follow an injury to the eye. The position of the injury bears no constant relation to the symptoms complained of, except, perhaps, that head injuries are rather more likely than others to give rise to cerebral symptoms.

Head Injuries in Relation to Nervous Disease.

I do not propose to consider the immediate result of severe head injuries, such as concussion or compression of the brain, but rather their remote effects. I will take as illustrations cases that have come recently under my own observation.

CASE 1.—The patient, a man aged 30, gave the following history. Five days before being seen he had been hit on the side of the head whilst playing cricket. He was batting at the time, and the ball hit him on the left temple. He was knocked over and lost consciousness for a few moments. He recovered quickly and was able to finish the game. That night he complained of severe headache and vomited several times. He remained in bed a day or so, but on the fourth day after the accident, when he was beginning to feel well again, he had a fit. Consciousness was not lost, and only the right side of the face was affected. Duration of the attack four minutes. Since the fit he had experienced slight difficulty in expressing himself. He had a second attack later in the day, and a third when I was examining him next day. The attacks were all similar in character and only involved the right side of the face. Examination revealed slight weakness of the right facial muscles and a slight degree of motor aphasia, the patient being often at a loss for a word and his vocabulary being limited. There was no other sign of organic nervous disease. The optic discs were normal and nothing could be felt at the seat of the injury.

From a consideration of the history of the case, in conjunction with the symptoms, a diagnosis of extradural hæmorrhage was made, the site of this being the lower part of the precentral gyrus and the origin of the hæmorrhage the anterior branch of the middle meningeal artery. Mr. Arthur Edmunds saw the case with me, and an operation was performed next day. A depressed fracture was found under the temporal muscle which we had not been able to feel before, and a considerable quantity of extradural clot was found when the depressed bone had been removed. This was removed and the dura opened to make sure that there was no subdural injury. None was found and the wound was closed. The patient made an uninterrupted recovery, and there were no more Jacksonian fits. Some weeks after the operation, however, the patient had a fit in every respect identical with those of idiopathic epilepsy. I did not hear of this till some months after the operation, by which time he had had several more attacks. He had not been put on bromides after the operation, as we reckoned on having removed the exciting cause of the fits. This I now think was a mistake, and in any similar case I should certainly advise the administration of bromides for a time after the operation. The patient was put on sodium bromide 20 gr. t.d.s., and there have been no more attacks.

---

[1] A paper read before the Windsor and District Medical Society.

The case will serve to introduce the difficult question of post-traumatic epilepsy. It is often very difficult to decide, though it was not in the case quoted, whether there is any causal relationship between head injury, or indeed any injury, and the subsequent development of epilepsy. I say "any" injury advisedly, as one has to remember that the mental or emotional shock, which often accompanies accident, may be in itself sufficient to produce epileptic attacks in specially predisposed individuals. Another important point which must not be lost sight of is that in a certain number of cases the head injury which may have been regarded as the *cause* of the fits is in reality the *result* of epilepsy, the patient having fallen in a first attack and injured himself. Again, epilepsy is a disease to which a certain amount of stigma is attached by the public. This is thought to be minimised if a definite cause can be found for the fits, any possible reflection on the parents being thereby obviated. Consequently old and forgotten head injuries are "remembered" subsequent to the first attack. This is specially noticeable in the case of children, in whom it is seldom difficult to find some occasion on which the head has been bumped.

The types of epilepsy that may follow injury may be either (*a*) focal or (*b*) general, including under this heading both grand and petit mal. Of these, however, the latter is much more rarely met with than the former. Focal fits, as in the case quoted, are almost always due to local pathological changes. Of these the commonest are depressed fractures, splinters of bone from the inner table, and blood-clot. In cases of long standing meningeal cysts or thickening and cortical scarring may be met with. In a few instances nothing is found at operation to account for the fits.

With regard to prognosis, the result of operative treatment in the focal cases is good if the injury is recent and the brain cortex uninjured, but is much worse where cysts have formed or the cortex has been injured. Where a scar exists in the cortex little good can be expected from the operation, and it is most inadvisable to interfere in any way with the brain tissue. Certain cases of Jacksonian epilepsy are reported from time to time as having been benefited by operation where nothing has been done beyond opening the skull, and in which nothing pathological has been found at the operation. In my experience such cases, if followed up, will usually be found to relapse into the *status quo ante*.

In cases of general epilepsy following head injury it is extremely doubtful if any operation ever does any permanent good. Statistics show that a definite history of trauma is obtainable in only a very small percentage of cases of general epilepsy, and although a few cases seem for a time to have benefited as the result of decompression operation, the improvement is not sufficiently lasting to encourage surgical intervention.

Traumatic Insanity.

In this case, again, there is a natural inclination on the part of relatives to seek for a definite cause for the condition, and blows or injury to the head are often suggested in this connexion. As a matter of experience very few patients can be shown to have become insane as the result of trauma, as Mott and others have clearly proved. It would appear, however, that trauma of one kind or another may be an important factor in determining the onset of mental disease, especially in the case of general paralysis. An instance in which trauma seems to have played a determining part in the development of mental symptoms has recently come under my observation.

CASE 2.—A patient, aged 19, was sent to me by Dr. P. W. Rowland, of Colchester, with the following history. The patient fell from his horse and hit the back of his head against the wooden wall of the riding school. He was dazed, but got on the horse again, and was able to finish the lesson. On reaching home he complained of severe headache, and vomited several times during the night. In this respect his symptoms were very similar to those of Case 1, but the sequel is different. From the time of the accident, so the parents declared, the boy had become morose, suspicious, unable to work, and in addition had developed delusions of persecution. Previous to the accident his mental condition had been perfectly normal. I saw him first about seven months after the accident, when he still complained of occipital pain, but the examination of the nervous system was negative. As he did not improve under treatment I had a consultation with Mr. Rawling, who kindly took him into St. Bartholomew's Hospital, and did a decompression operation. The cerebrospinal fluid was found under increased pressure, but there was no evidence of any gross cerebral lesion. The operation has not improved the mental condition at all, and the boy is now in an asylum.

With regard to the question of advising operation in such cases certain facts must be considered. In a few cases operation has been found to relieve mental symptoms that have arisen immediately following a head injury. In such cases some definite lesion has usually been found at operation, such as depressed fracture, blood clot, and so on. In others nothing has been discovered beyond some increase in the cerebrospinal fluid, with œdema of the meninges. Under the circumstances I think that one is justified in advising operation when sufficient trial has been made of proper medical treatment without any benefit. In the majority of cases the results will no doubt be disappointing, but no harm will have been done provided the operation has been performed by an experienced surgeon. In a certain number of cases good results will occur, sufficiently often in my opinion to justify the operation. One cannot pass on without mentioning the famous American crowbar case, in which dementia followed injury to the frontal lobes. The accident in this case was evidently the cause of the mental change, but one must remember that it had produced a gross cerebral lesion.

Post-traumatic Headache.

Headache of a very intense and intractable type is frequently the result of severe head injury. This symptom is often combined with others, which together make up the clinical picture of traumatic neurasthenia, but the headaches may exist alone. They are as a rule intermittent, localised at the onset of the attack, but later become diffused all over the head. The following cases illustrate the types to which I refer.

CASE 3.—A man, aged 39, had a bad fall when riding, as a result of which he lost consciousness and was convulsed on the left side of the body. He remained unconscious
several days, and later had complete amnesia for the
of the three weeks immediately following the accid
a result of the accident he became liable to att
severe headache, localised at their onset to th
but after a time becoming diffused all ov
memory was affected, so that he was un
duties, on which he was very keen
had become impossible, and he fe

c

cases of enteric fever and pleural effusion gave negative results; 2 of the effusion cases had definite tuberculous signs.

The best reactions are to be found in well-nourished individuals, especially children; here Chlumsky is in agreement. Old-standing cases and old subjects usually fail; this is possibly due to the inability of the skin to react, resulting from either chronicity of toxæmia or from trophic changes in the skin concurrent with advancing years. The greater susceptibility of the female sex points to delicacy of the skin as a factor. I also made observations to ascertain whether fair individuals, as opposed to those possessing a larger share of pigment, were more liable to respond, but no relation exists. It is well established that increase in dose of tuberculin injections may convert a failure into a response; both the skin and conjunctival reactions might give better results if the dose were regulated. Among the tuberculous cases all the positive results except 5 occurred under the age of 14 years, the majority of failures occurring between 15 and 40 years of age.

In order to form a more close comparison between the von Pirquet reaction and the Moro test I applied both in a series of 132 cases. Of these cases 51 were definitely tuberculous, but only 13 out of these reacted to both, and 20 failed to respond to either, but I have never observed a tuberculous case which reacted to the ointment fail also to react to the von Pirquet method. Moro reports a similar experience. Out of my cases clinically free from tuberculosis 6 responded to both tests, 50 failed to react to either. Whereas 23 reacted to the scarification only 2 non-tuberculous cases gave results with the ointment only. These results may be more clearly shown in tabular form:—

132 Cases to which Two Tests were Applied.

Tuberculous cases giving von Pirquet and Moro reactions	13	
„ „ „ von Pirquet reaction only	18	
„ „ „ Moro reaction only	0	
„ „ „ failing with both...	20	—51
Non-tuberculous cases giving von Pirquet and Moro reactions ...	6	
„ „ „ von Pirquet reaction only	23	
„ „ „ Moro reaction only	2	
„ „ „ failing with both...	50	—81

From the above it is clear that the von Pirquet test gives a larger number of reactions among tuberculous subjects than the ointment test, but at the same time it gives a much larger number of false results among non-tuberculous individuals. These two skin reactions are much inferior to the ophthalmic test, which gives a large percentage of true results, whilst reactions in non-tuberculous subjects are not very frequent.

Conclusions.—1. The ointment test is exceedingly inaccurate. 2. It does not give nearly so many reactions in non-tuberculous cases as the von Pirquet test. 3. Most reactions are obtained in women and children. 4. It is of no value in prognosis. 5. It more often fails in tuberculous cases than the cutaneous reaction. 6. Late reactions have no clinical significance. 7. Tuberculous cases which respond to the ointment also react to the von Pirquet method. 8. Pyrexia does not interfere with the reaction. 9. The test is free from danger.

Bath.

A CASE OF POST-OPERATIVE OSTEOMYELITIS OF THE FRONTAL BONE.

RECOVERY AFTER WIDE REMOVAL OF THE DISEASED BONE.

By W. G. PORTER, M.B., B.Sc. Edin., F.R.C.S. Edin.,
SURGEON, EAR AND THROAT DEPARTMENTS, ROYAL HOSPITAL FOR SICK CHILDREN, AND EYE, EAR, AND THROAT INFIRMARY, EDINBURGH.

Osteomyelitis of the frontal bone is not a very uncommon complication of frontal sinus suppuration, but it is an extremely dangerous one. Dr. D. Mackenzie,[1] in a recent exhaustive account of the condition, states that in 20 post-operative cases which he collected he had found no case recorded in which the patient had recovered; while in spontaneous cases the results were not so bad, 7 having recovered out of 21 cases after appropriate surgical treatment. The following case is, so far as I know, the first post-operative case in which recovery has ensued, and it accordingly seems desirable to give a somewhat detailed account of it.

The patient, a married woman aged 46, was referred to me from the Eye Department of the Edinburgh Eye, Ear, and Throat Infirmary by Dr. J. V. Paterson. She complained of double vision and a swelling just above the right eyeball towards the external canthus, and there was also definite proptosis. After examination a diagnosis was arrived at of empyema of the right frontal sinus and ethmoidal labyrinth, with orbital abscess.

Killian's operation was performed on May 14th, 1912. The frontal sinus was found to be filled with creamy muco-pus (pure culture of hæmolytic long-chained streptococcus obtained), but the lining membrane was not thickened; hence it was thought that the case was one of infected mucocele. The floor of the sinus had given way rather far back, and pus was lying on the orbital periosteum, which at this spot was covered with granulations; there was a very well-marked orbital extension—it was fully an inch and a half in depth. In smoothing off the bone close to the inter-sinus septum the latter was unfortunately cracked, exposing the sinus on the opposite side. The wound was entirely closed and healed by first intention. Three weeks later the upper eyelid became œdematous; the wound was reopened and a quantity of pus evacuated. The discharge continued in spite of the administration of an autogenous vaccine and of endeavours to obliterate the sinus by pressure.

A second operation was performed on Oct. 3rd, 1912. The inner end of the bridge was removed, and a sinus was traced to the hole in the septum, where pus was seen coming from the left frontal sinus. The outer part of the right frontal sinus was obliterated by dense fibrous tissue, as was the opening into the nose. A Killian's operation was thereupon performed on the left frontal sinus, which also had a deep orbital extension. The inner part of the incision was left open after the operation, sutures being passed, but not tied for 48 hours, there being then no discharge. The wound healed at once, but a few days later the upper eyelid became swollen, and pain was felt at night; there was, however, no pyrexia.

On Nov. 11th the swelling became more marked, and there was great tenderness on pressure over the bridge. The wound was reopened; the inner end of the bridge was divided, and it was then found to be loose, a sequestrum being removed which consisted of the outer end of the bridge and the upper margin of the orbit external to it. (Fig. 1.) No pus was evacuated. The wound was left freely open and loosely packed. The pain was not relieved by the operation and the upper eyelid remained swollen. The temperature varied between 98·4° and 99 2° F.

On Nov. 17th œdema of the skin was noted over the frontal sinus; this spread rapidly, and on the 20th extended up to the hair margin and across the middle line; there was, however, very little discharge from the wound, which was still kept widely open. It was believed that osteomyelitis had set in, and wide removal of the frontal bone appeared to offer the only hope of recovery. Dr. A. Logan Turner, who very kindly saw the patient with me in consultation, concurred in the diagnosis and in the proposed treatment. Accordingly, on the following day a mesial incision was made upwards from the root of the nose, and a triangular flap of skin and periosteum turned back. The bone appeared glazed on the surface; a large circle of bone was removed with hammer and gouge; the bone was about half an inch thick, very soft and vascular, and did not give the usual ring when struck (Fig. 1). The margins of the bone were further removed with bone forceps until a firmer consistence and diminished vascularity appeared to show that the limits of disease had been reached. There was no pus in the substance of the bone, and the dura appeared healthy. The skin flap was then replaced and fixed in position by a few interrupted sutures. There was considerable discharge from the wound for some days; the pus was examined, a staphylococcus pyogenes aureus isolated, and an autogenous vaccine made. Healing gradually took place, and was undoubtedly assisted by the administration of the vaccine. Five doses were given in all, increasing from 50 to 400 millions, the first being administered on Nov. 26th and the last on Jan. 6th, 1913. The patient had no further trouble in the operation area, and she remained in excellent health until Nov. 19th, when she had an attack of pneumonia which carried her off in a few days. The photograph of the patient (Fig. 3) was taken a month after the wound had healed: it hardly brings out the marked flattening on the left side of the head. This was concealed by a wig when going about.

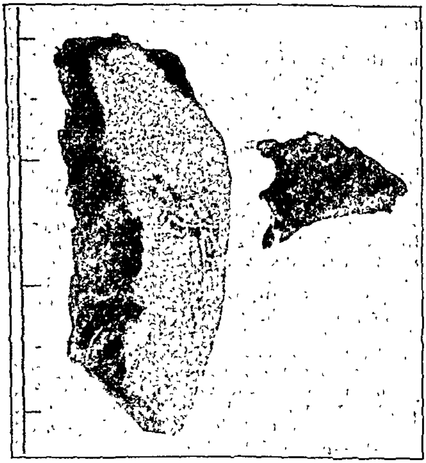
FIG. 1.



Tl [illegible] of bone was removed at the last operation [illegible]

A small block of bone was taken for microscopic examination from the large piece removed at the last operation. I am indebted to Mr. John Fraser, assistant surgeon to the Royal Hospital for Sick Children, Edinburgh, for having prepared the sections, which were cut from the block after it had been decalcified and embedded in celloidin, and I take this opportunity of thanking him most heartily for his valued services. The sections (Fig. 2) were submitted to Dr. Theodore Shennan, pathologist to the Royal Infirmary, Edinburgh, and I am also most grateful to him for the trouble he has taken in examining them and for the following report which he has very kindly given me:—

"The spaces in the bone in parts are wide, in others very small. There has probably been some absorption in the case of the larger. In some parts there is definitely a deposit of a thin layer of bone on the inner surface of the spaces, and a common feature is the presence of a regular layer of osteoblasts in this situation. The fat in the marrow is of small amount, being represented by only a few fat cells in any one space, and in some spaces the fat has altogether disappeared. It has been replaced by young vascular connective tissue consisting chiefly of long fibroblasts, the long axes of which are arranged parallel to the surface of the space. This young connective tissue is found chiefly round the periphery of the space, the central part being full of cells, chiefly polymorphonuclear leucocytes, but there are also large mononuclear cells of the granular series and occasional giant [illegible] a local bone marrow reaction (though this cannot be excluded by these celloidin sections), and the condition as being one of chronic osteitis with a recent more acute exacerbation."

FIG. 2.

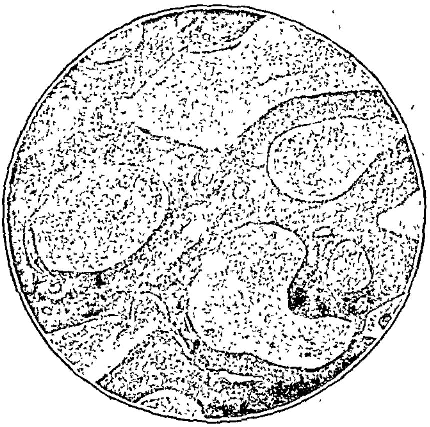


Photo micrograph of section of bone.

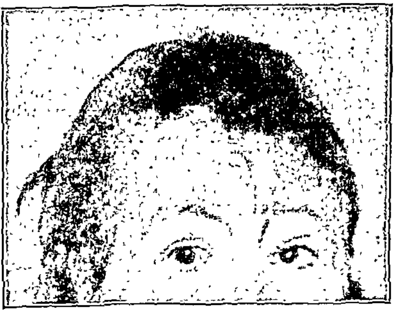
FIG. 3.



Photograph of upper part of patient's head after recovery.

Remarks.—There can, I think, in this case be little doubt as to the accuracy of the diagnosis, at any rate as judged by the clinical phenomena. The picture was indeed typical of osteomyelitis in its early stages; the classical sign of osteomyelitis was present—namely, œdematous swelling beyond the confines of the sinus, while the onset was also

VACCINES FROM THE STANDPOINT OF THE PHYSICIAN.[1]

By THOMAS J. HORDER, M.D. Lond., F.R.C.P. Lond.,
ASSISTANT PHYSICIAN, ST. BARTHOLOMEW'S HOSPITAL.

I. *Introductory.*

I fully endorse the opinion of the council of this section that the time has arrived when the subject of vaccine therapy may be usefully discussed by its members. It is natural that conclusions drawn from the experiences of the physician should be arrived at more slowly than conclusions drawn from the laboratory researches of the bacteriologist. Without being invidious, I think these slower conclusions are likely to be more sure. I will venture to say that as the physician is more free from theories, provided he is also free from prejudice, he is the better judge of practical results. The physician is face to face with the patient throughout the treatment of his disease; he is the direct witness of the struggle and of the issue. Surely the final verdict must be his? If this is true it is, then, equally true that to occupy this high judicial position in respect of so important a matter as we are to-day discussing implies a responsibility none the less high. It behoves us to throw away all bias and to exercise our best judgment after a thorough trial of the matter under consideration. As I said, I think the physician has now had time to test the new therapeutic agent and should be able to speak with some degree of assurance of his results. He is no longer hustled by those who at one time accused him of gross neglect, as though he were deliberately refusing to his patient the benefit of a remedy of proved usefulness; nor is he to-day ridiculed by others who pointed to him as the one stumbling-block in the real advance of scientific medicine. These and other similar errors of judgment have now even less than a historic interest in the growth of specific therapy. That sudden intrusion of the skilled bacteriologist into the sphere of clinical medicine was a sight as pathetic as would be the invasion of the bacteriological laboratory by the physician. The difficulty was only a temporary one, and has been settled in the only way that was ever possible in the patient's interests—by a frank coöperation between the laboratory and the clinique. This partnership yields results that bid fair to stamp it as the final and satisfactory solution of the problem.

II. *Recent Growth of Vaccine Therapy.*

Freed from the incubus under which it first laboured—the hypothesis of the opsonic index—there has been an immense increase in the amount of vaccine therapy undertaken during the past five years. It is uncertain if we may conclude anything from this change in medical opinion in favour of the new remedy. At first sight the growing popularity of inoculation treatment amongst practitioners suggests that its utility is thereby demonstrated. But on a further view we become aware of the fact that to a large extent this accession of practical interest on the part of the doctor is due to the forcing of his hand by the patient. This, and a natural desire not to be left behind, may be responsible for much of the increase in the bulk of vaccine therapy as seen to-day, rather than honest conviction based upon personal experience. Just as hundreds of us joined the vogue for soured milk in the treatment of intestinal dyspepsia a few years back, and hundreds of us join the vogue for treating constipation by paraffin to-day, for reasons of necessity rather than conviction, so many of us inoculate our patients because it is expected of us rather than because we feel it is the best way to cure them. In short, inoculation treatment is fashionable—it has "caught on" with the public—and it does not yet appear what the permanent place of the therapeutic measure will be. It must be confessed that a large amount of vaccine therapy is of the most discursive and slipshod kind; so desultory and unsystematised is it that it must be wholly excluded from any analysis made for purposes of assessing the results of the method in treatment.

III. *Three Grades of the Remedy.*

It was inevitable that the growing demand for vaccines at a price which put them within the reach of patients whose means could not permit accurate bacteriological diagnosis and the preparation of an autogenous vaccine would lead to the supply of "stock vaccines." And in the course of time it was manifestly desirable that the stock vaccines should be prepared with a view to their being "polyvalent"—i.e., that they should be made from a mixture of strains of the particular micro-organism concerned. In addition to the legitimate sphere created for such preparations by the patient's status, there is an actual necessity for them in certain cases of infection in which no material is available for the purpose of autogenous vaccine, but in which experience makes the nature of the infection highly probable. Stock vaccines are also required for prophylactic purposes. The latest demand has been for the addition to the list of vaccines of substances of more questionable value, and chemists now supply stock preparations which are mixtures of the endotoxins of several different micro-organisms: we have arrived at "phylacogens." This is a frank submission to the fact that there are many medical men who feel that something should be injected into their patients, but that beyond this they are not prepared to go. To what degree this submission prostitutes the main principles of vaccine therapy, or whether, after all, the practice of using such substances may not be quite reasonable in the present state of medical training, is perhaps a fit subject for our discussion. The use of phylacogens clearly demonstrates one thing—that the fear of ill-effects from the introduction of microbic poisons into the system has to a large extent died out, both in the mind of the patient and of the doctor, and this must apply as well to the micro-organism which is, as well as to those that are not, causing the disease.

We note, therefore, that the evolution of vaccine therapy has led to the production of *three grades* in the particular instrument made in the bacteriological workshop: autogenous vaccines, stock vaccines, and "phylacogens." That these three grades correspond with three degrees of efficiency there is very little doubt, and in estimating the good effects of vaccine therapy it is obviously unfair to attach any importance to failures following the use of the third grade of preparation, which must be regarded as one of the gambles of science, the hit or miss of medical practice. Even the results of the stock vaccines should not be too closely regarded in judging this question. The merits of vaccine therapy as a curative measure rest almost entirely upon the results obtained by the use of the first grade of preparation—upon autogenous vaccines conscientiously prepared after a full investigation of materials obtained from the patient with scrupulous care.

---

[1] the introduction to a discussion at the Medical Section of the [illegible] of Medicine on Jan. 27th, 1914.

IV. *Too Much must not be Expected.*

It is probably not too much to say that in a number of diseases of undoubtedly infective origin the limitations of the vaccine method as at present known have been reached and fully demonstrated. By no arrangement of dose or of interval that I have been able to devise has it been possible to free the urinary tract from B. coli in old-standing cases of chronic infection by this micro-organism, nor the bronchial tract from its mixed and changing flora in chronic bronchitis. But against this should be set the fact, for I believe it to be a fact, that when all that is possible has been done in the way of non-specific measures in the treatment of these affections, the careful use of a systematic course of vaccines leads, in the majority of cases, to a definite further improvement in the general condition, and to a less extent in the local defect. No doubt the difficulty is largely one of drainage; in chronic colon bacillus infection of the urinary tract it is not often a simple cystitis with which we have to deal: vesical sacculi, the prostatic crypts, and the kidney pelvis afford continued refuge for bacilli; and in chronic infection of the bronchial tract there is often a diffuse dilatation of the tubes, if there is not actual bronchiectasis. Effective drainage is of greater fundamental importance in such diseases as these than the most ingeniously arranged course of vaccine therapy. Some time ago I outlined with some care a full programme of treatment in a tedious case of bronchiectasis, and the programme included a course of vaccines prepared against the dominant elements of the flora present in the sputa at the time. Three months later I saw the patient again and shared the pleasure he himself expressed at his improved condition. It was doubtless a salutary thing for my humility to know that, having been compelled to defer his treatment on account of a temporary change of residence, the only point he had observed in my programme, and that very religiously, was to adopt a certain posture I had shown him for half an hour each day during his morning cough.

Too much uniformity of results is often expected from vaccine treatment. The sceptic should remember the complexity of the causal factors in so many infective processes and the variations even in the natural course run by them. He should also remember the difficulties there are in ensuring the proper co-relation of the vaccine used with the pathological condition under consideration. Finally, he should not be over hasty for results. Patience is necessary in order to determine the best mode of calling out the specific response. A bias against vaccines diminishes the physician's chances of success; he is apt to make one of two mistakes: he either proceeds with such unreasonable caution that there is no assurance at any time that he is dealing with more than subminimal doses, or he pursues a too rigid adherence to a particular scheme of dosage and of intervals which has been laid down as a tentative guide rather than as an inviolable law.

V. *Difficulty of Assessing Results.*

The therapeutic argument is probably the most difficult with which we have to deal in connexion with all diseases. In connexion with infective processes it is perhaps more difficult than in any other condition, for two reasons. Most infective processes are capable of spontaneous recovery, and in the majority of them we are doing other things to assist recovery besides giving vaccines. Both of these facts are freely quoted as evidence against the utility of vaccine therapy. And it may be allowed that single instances of recovery after the employment of vaccines in any disease would count for nothing in the experience of any of us. It is only when we see repeated instances of benefit directly following the use of inoculation in cases which had previously remained stationary or had been losing ground that we realise the results are *propter* and not merely *post hoc*. When we have employed all the other measures that are available and the net result is, perhaps, some gain which the patient slowly dissipates, or perhaps no gain at all; and when we then add the specific stimulus of an appropriate vaccine, and witness a specific response that leads to further gain of a definitely progressive sort—it is then that we feel it is right to say that the progress is due to the vaccine. And when such a sequence is repeated again and again in our experience our conviction becomes confirmed and definitely established.

The failures of vaccine therapy are probably more numerous than its successes. I think this is probably true, even if we discard as worthless for analytical purposes a list of instances in which the diagnosis or the bacteriological technique, or both, were faulty. Yet this fact does not of itself prevent my saying that I think we have in vaccine therapy a weapon of enormous value in the war we wage upon the causes of infective diseases. I am confident that the seeing eye can detect quite clearly, here and there, innumerable instances in which the patient has made a specific response to his inoculations, and has thereby been cured of his infection. It is as though one wandered up and down a long passage into which many locked doors opened, carrying a key and trying the doors with it. Many refuse to open: the key does not fit. Then there comes one where the key turns smoothly and the door opens easily. This accurate fitting of lock and key illustrates the specific stimulus and response of a vaccine given in a successful case. The question we are discussing is, primarily, Does any key fit any door? A secondary question will be, How frequently are we able to find the proper key? I have no doubt myself as to the efficacy at times of vaccine therapy. I am as disappointed with results in the mass as most others are. But the primary question is of much greater importance than the secondary because it involves a principle. The secondary question may be answered more satisfactorily as time proceeds and newer methods are introduced. With all the activity shown in vaccines during the past ten years it must be remembered that a great deal of it, as already remarked, has been too crude to serve as a basis for comment.

VI. *Factors Counting for Success.*

In exchange for a frank admission that I consider vaccine therapy a most valuable addition to the physician's powers, I may perhaps be allowed to say that I think this value is in direct proportion to the care and judgment bestowed upon the diagnostic problem. Every therapeutic measure is able to earn an evil reputation if it and the disease process are ill-adjusted. This is no more the fault of the remedy than is an evil reputation earned by the same measure because a fanatic regards it as a panacea when in reality it has only a limited application. If, then, I recount the factors which I regard as leading to success in vaccine therapy I shall speak first of—
